Accuracy of the Tracy-Widom limits for the extreme eigenvalues in white Wishart matrices

Zongming Ma

August 30, 2010

Abstract

The distributions of the largest and the smallest eigenvalues of a $p$-variate sample covariance matrix $S$ are of great importance in statistics. Focusing on the null case where $nS$ follows the standard Wishart distribution $W_p(I,n)$, we study the accuracy of their scaling limits under the setting: $n/p \to \gamma \in (0, \infty)$ as $n \to \infty$. The limits here are the orthogonal Tracy-Widom law and its reflection about the origin.

With carefully chosen rescaling constants, the approximation to the rescaled largest eigenvalue distribution by the limit attains accuracy of order $O(\min(n,p)^{-2/3})$. If $\gamma > 1$, the same order of accuracy is obtained for the smallest eigenvalue after incorporating an additional log transform. Numerical results show that the relative error of approximation at conventional significance levels is reduced by over 50% in rectangular and over 75% percent in ‘thin’ data matrix settings, even with $\min(n,p)$ as small as 2.

Key Words and Phrases: Eigenvalues of random matrices, Laguerre orthogonal ensemble, principal component analysis, rate of convergence, Tracy-Widom distribution, Wishart distribution.

1 Introduction

Understanding the behavior of the extreme eigenvalues of a sample covariance matrix $S$ is important in a large number of multivariate statistical problems. As an example, consider one of the most common inference problems: testing the null hypothesis that the population covariance is identity. Roy’s union intersection principle [29] suggests that we reject the null hypothesis for large values of the largest eigenvalue of $S$ (or for small values of the smallest eigenvalue). Naturally, the next question is: how should the $p$-value be calculated?

To address this issue, and many others, it is necessary to examine the null distributions of the extreme sample eigenvalues. In this paper, we restrict ourselves to the Gaussian framework. In particular, let $X$ be an $n \times p$ data matrix whose row vectors are i.i.d. samples from the $N_p(0, I)$ distribution. The $p \times p$ matrix $A = X’X$ then follows a standard Wishart distribution: $A \sim W_p(I, n)$, and is called a (real) white Wishart matrix. The ordered eigenvalues of $A$ are denoted by $\lambda_1 \geq \cdots \geq \lambda_p$. Our interest lies in $\lambda_1$ and $\lambda_p$, as $A = nS$.

The exact evaluation of the marginal distributions of these eigenvalues is difficult, even in the null case considered here. See, for example, Muirhead [24, Section 9.7]. An alternative approach is to approximate them by their asymptotic limits. For the problem we are concerned with, Anderson [2] Chapter 13] summarized the classical results under the conventional asymptotic regime: $p$ holds fixed and $n$ tends to infinity.
However, for a wide range of modern data sets (microarray data, stock prices, weather forecasting, etc.), the number of features $p$ is very large while the number of observations $n$ is much smaller than or just comparable to $p$. For these situations, the classical asymptotics is not always appropriate and different asymptotic theories are needed. Borrowing tools from Random Matrix Theory, especially those established by Tracy and Widom [32, 33, 34], Johnstone [15] showed that under the asymptotic regime

$$p \to \infty, n = n(p) \to \infty \text{ and } n/p \to \gamma \in (0, \infty),$$

the largest eigenvalue $\lambda_1$ in $A$ has the weak limit

$$\frac{\lambda_1 - \mu_p}{\sigma_p} \xrightarrow{D} F_1,$$

where the centering and scaling constants are defined as

$$\mu_p = (\sqrt{n - 1} + \sqrt{p})^2, \quad \sigma_p = (\sqrt{n - 1} + \sqrt{p}) \left( \frac{1}{\sqrt{n - 1}} + \frac{1}{\sqrt{p}} \right)^{1/3}.$$

Here $F_1$ denotes the orthogonal Tracy-Widom law [33], the scaling limit of the largest eigenvalue in real Gaussian Wigner matrices. Slightly prior to [15], as a byproduct of his analysis on the random growth model, Johansson [14] proved that the scaling limit for the largest eigenvalue in complex white Wishart matrix is the unitary Tracy-Widom law $F_2$. Recently, El Karoui [9] extended the asymptotic regime (1) to include the cases where $n/p \to 0$ or $\infty$. For the smallest eigenvalue, when $\gamma > 1$, Baker et al. [3] showed that the reflection of $F_2$ about the origin is the scaling limit for complex Wishart matrices, and Paul [28] gave the Tracy-Widom limits in the case where $n/p \to \infty$ for both complex and real Wishart matrices.

Although this type of asymptotic result has emerged only recently in the statistics literature, it has already found its relevance to applications with modern data. For instance, based on [2], Patterson et al. [27] developed a formal procedure for testing the presence of population heterogeneity with SNP (single nucleotide polymorphism) data.

From a statistical point of view, to inform the use of any asymptotic result in practice, we need to understand how closely the asymptotic limit approximates the finite sample distributions. In the motivating example, this dictates the accuracy of the nominal $p$-value.

In this paper, we first establish a rate of convergence result for the Tracy-Widom approximation to the distribution of the rescaled largest eigenvalue, but with more carefully chosen constants than (3). Set $a \land b = \min(a, b)$ and $m_\pm = m \pm \frac{1}{2}$. We show that modifying the centering and scaling constants to

$$\mu_{n,p} = (\sqrt{n} + \sqrt{p})^2, \quad \sigma_{n,p} = (\sqrt{n} + \sqrt{p}) \left( \frac{1}{\sqrt{n}} + \frac{1}{\sqrt{p}} \right)^{1/3}$$

results in better approximation: the difference between the distribution of $(\lambda_1 - \mu_{n,p})/\sigma_{n,p}$ and $F_1$ reduces to ‘second order’, being $O((n \land p)^{-2/3})$ rather than $O((n \land p)^{-1/3})$ that would apply by using (3). See Theorem 1. Numerical work in Section 2.2.1 suggests that the improvement is substantial.

Further assuming $\gamma > 1$ in (1), we find that, with a log transform, the scaling limit of $\log \lambda_p$ is the reflected Tracy-Widom law $G_1$ (defined by $G_1(s) = 1 - F_1(-s)$) [28]. Moreover, with appropriate rescaling constants, the accuracy of the limit also reaches second order: $O(p^{-2/3})$. See Theorem 2 and Section 2.2.2.
In the literature, El Karoui [10] established a parallel result for Johansson’s theorem for the largest eigenvalue on the complex domain and Choup [6] studied the same problem via an Edgeworth expansion approach. Recently, Johnstone [16] obtained both scaling limit and convergence rates for the extreme eigenvalues of an $F$-matrix, on both complex and real domains. As is usual in the Random Matrix Theory literature, results on the real domain are founded in part on those for complex data but require significant additional constructs and arguments: this is explained for our setting in Sections 3 and 4.

The rest of the paper is organized as follows. In Section 2, we present theorems for both the largest and the smallest eigenvalues, together with supporting numerical results, related statistical settings, a real data example and a brief discussion. Section 3 proves the theorem on the largest eigenvalue, and Section 4 sketches the proof of the one on the smallest eigenvalue. Finally, Section 5 establishes necessary Laguerre polynomial asymptotics which is first used without proof in Section 3. Technical details are collected in Appendix.

2 Main Results and Their Applications

In this section, we first state two main theorems of this paper, which are concerned with the convergence rates of the largest and the smallest eigenvalues in finite Wishart matrices to their Tracy-Widom limits. The theorems are then complemented and further justified by a series of numerical experiments, in which the Tracy-Widom approximation is reasonably good even when $n$ and/or $p$ are as small as 2. After that, we review several related statistical settings and consider a real data example. Finally, we end the section with a brief discussion.

2.1 Main Theorems

We begin with the largest eigenvalue, for which we have the following rate of convergence result.

**Theorem 1.** Let $A \sim W_p(I, n)$ with $n \neq p$ and $\lambda_1$ its largest eigenvalue. Define $$(\mu_{n,p}, \sigma_{n,p})$$ as in (4). Under condition (1), for any given $s_0$, there exists an integer $N_0(s_0, \gamma)$, such that when $n \land p \geq N_0(s_0, \gamma)$ and is even, for all $s \geq s_0$, $$|P\{\lambda_1 \leq \mu_{n,p} + \sigma_{n,p}s\} - F_1(s)| \leq C(s_0)(n \land p)^{-2/3}\exp(-s/2),$$ where $C(\cdot)$ is continuous and non-increasing.

We also obtain an analogous result for the smallest eigenvalue. Refine condition (1) to

$$p \to \infty, p + 1 \leq n = n(p) \to \infty \text{ and } n/p \to \gamma \in (1, \infty).$$

Define $$\mu_{n,p}^\ast = \left(\sqrt{n^{-} - \sqrt{p^{-}}}ight)^2, \quad \sigma_{n,p}^\ast = \left(\sqrt{n^{-} - \sqrt{p^{-}}} \left(1/\sqrt{p^{-}} - 1/\sqrt{n^{-}}\right)^{1/3}, \right.$$

and let

$$\tau_{n,p}^\ast = \frac{\sigma_{n,p}^\ast}{\mu_{n,p}^\ast}, \quad \nu_{n,p}^\ast = \log(\mu_{n,p}^\ast) + \frac{1}{8} \left(\tau_{n,p}^\ast\right)^2.$$  

Then, we have the following theorem.

**Theorem 2.** Let $A \sim W_p(I, n)$ with $n - 1 \geq p$ and $\lambda_p$ its smallest eigenvalue. Define $(\nu_{n,p}^\ast, \tau_{n,p}^\ast)$ as in (6). Under condition (5), we have

$$\frac{\log \lambda_p - \nu_{n,p}^\ast}{\tau_{n,p}^\ast} \overset{D}{\to} G_1$$
with $G_1(s) = 1 - F_1(-s)$ the reflected Tracy-Widom law.

In addition, for any given $s_0$, there exists an integer $N_0(s_0, \gamma)$, such that when $p \geq N_0(s_0, \gamma)$ and is even, for all $s \geq s_0$,

$$\left| P \{ \log \lambda_p \leq \nu_{n,p}^- - \tau_{n,p}^- s \} - G_1(-s) \right| \leq C(s_0)p^{-2/3}\exp(-s/2),$$

where $C(\cdot)$ is continuous and non-increasing.

While we only prove rigorous bounds for even $p$, numerical experiments show that the approximation works just as well in the odd case, and for the largest eigenvalue, also in the square case. See Tables 1 and 2.

### 2.2 Numerical Performance

An important motivation for the current study is to promote practical use of the Tracy-Widom approximation. To this end, we conduct here a set of experiments to investigate its numerical quality.

#### 2.2.1 The largest eigenvalue

**Distributional approximation.** We first computed the empirical cumulative probabilities of $\lambda_1$ (after rescaling), at a collection of $F_1$ percentiles, using $R = 40,000$ replications. This is done for three different categories of $(n, p)$ combinations: (1) the square case, where $n = p = 2, 5, 25$ and 100; (2) the rectangular case, where $p = 2, 5, 25$ and 100, and $n/p$ is fixed at 4:1; (3) the ‘thin’ case, where $p = 5$ and 10 but $n/p$ could be as high as 100:1 and 1000:1. For comparison purpose, we rescaled $\lambda_1$ using both the new constants (4) and the old ones (3). The results are summarized in Table 1.

Numerical accuracy with the new constants could be viewed from two aspects. First, for the conventional significance levels of 10%, 5% and 1% which correspond to right tails of the distributions, the approximation looks good even when $p$ is as small as 2! In addition, it improves as $p$ becomes larger and starts to match the finite distributions almost exactly when $p$ is no greater than 25. See the last three columns of Table 1. Second, when $p$ is large, for instance, in the $100 \times 100$ and $400 \times 100$ cases, $F_1$ provides reasonable approximation over the whole range of interest.

As regards the comparison between different rescaling constants, neither choice seems superior to the other in the square cases (see the first block of Table 1). However, when the ratio $n/p$ is changed to 4:1 or higher (see the second and the third blocks), the improvement by using new constants (4) is self-evident.

As a remark, better performance on right tails and improvement by using the new constants, as reflected in this simulation study, agree well with the mathematical statement in Theorem 1.

**Approximate percentiles.** We can also use $F_1$ to calculate approximate percentiles for the finite distributions, whose accuracy can be measured by the relative error $r_\alpha = \theta_\alpha^{TW}/\theta_\alpha - 1$. Here, $\theta_\alpha$ is the exact $100\alpha$-th percentile of the rescaled largest eigenvalue in the finite $n \times p$ model and $\theta_\alpha^{TW}$ is its counterpart from $F_1$.

In Fig. 1, we plot $r_\alpha$ for $\alpha = 0.95$ and 0.99, with $p$ ranging from 2 to 5 and $n$ from 2 to 50. Although $n \wedge p$ is no greater than 5, the approximation is reasonably satisfactory. For the 95-th percentile, $|r_{0.95}|$ ranges from 5% to 10% for most cases and slightly exceeds 10% only when

---

1. In some sense, this category could also be thought of as in the situation where $n/p \to \infty$ as discussed in [9].
Table 1: Simulations for finite $n \times p$ vs. Tracy-Widom limit: the largest eigenvalue. For each $(n, p)$ combination, we show in the first row empirical cumulative probabilities for $\lambda_1$, rescaled by (4), and the second row, with parentheses, rescaled by (3), both computed from $R = 40,000$ repeated draws from $W_p(n, I)$ using the method in [7]. Conventional significance levels are highlighted in bold font and the last row gives approximate standard errors based on binomial sampling. $F_1$ was computed by the method in [8] with percentiles obtained via inverse interpolation.

$p = 2$ and the $n/p$ ratio is high. The approximation works even better for the 99-th percentile, with $|r_{0.99}| \leq 5\%$ for most cases. Due to computational limitation [20], we could not obtain exact percentiles when $n$ and $p$ are large. We expect the approximate percentiles to become more accurate as a consequence of better distributional approximation.

### The smallest eigenvalue

For the smallest eigenvalue, we perform a simulation study to investigate the distributional approximation. We chose two $n/p$ ratios: 2:1 and 4:1, both with $p = 2, 5, 25$ and 100. For each $(n, p)$ combination, we used $R = 40,000$ replications. The simulation results shown in Table 2 demonstrate similar performance as in the case of the largest eigenvalue and agree well with Theorem 2.

Table 2: Simulations for finite $n \times p$ vs. Tracy-Widom limit: the smallest eigenvalue. For each $(n, p)$ combination, empirical cumulative probabilities are computed for $(\log \lambda_p - \nu_{n,p}^-)/\tau_{n,p}^-$ using $R = 40,000$ draws from $W_p(I, n)$. Methods for sampling, computing $F_1$ and obtaining percentiles are the same as in Table 1. Conventional significance levels are highlighted in bold font and the last line gives approximate standard errors based on binomial sampling.

2.3 Related Statistical Settings

Here, we review several settings in multivariate statistics to which our results are applicable. Throughout the subsection, we only use the largest eigenvalue to illustrate.

**Principal component analysis.** Suppose that $X = [X_1, \cdots, X_n]'$ is a Gaussian data matrix. Write the sample covariance matrix $S = (n-1)^{-1}X'HX$, where $H = I - n^{-1}11'$ is the centering matrix, principal component analysis (PCA) looks for a sequence of standardized vectors $a_1, \cdots, a_p$ in $\mathbb{R}^p$, such that $a_i$ successively solves the following optimization problem:

$$\max \{a'Sa : a'a_j = 0, j \leq i\},$$
where \(a_0\) is the zero vector. Then, successive sample eigenvalues \(\hat{\lambda}_1 \geq \cdots \geq \hat{\lambda}_p\) satisfy \(\hat{\lambda}_i = a_i^\prime S a_i\). One basic question in PCA application is testing the hypothesis of isotropic variation, i.e., the population covariance matrix \(\Sigma = \tau^2 I\). For simplicity, assume that \(\tau^2 = 1\) (otherwise we divide \(S\) by \(\tau^2\)). Then \((n-1)S \sim W_p(I, n-1)\). The largest eigenvalue \(\hat{\lambda}_1\) of \(S\) is a natural test statistic under the union intersection principle. Our result applies to \((n-1)\hat{\lambda}_1\). If \(\tau^2\) is unknown, we could estimate it by \(\text{tr}S/p\). See [23].

**Testing that a covariance matrix equals a specified matrix.** Suppose that \(X = [X_1, \cdots, X_n]^\prime\) has its row vectors i.i.d. samples from the \(N_p(\mu, \Sigma)\) distribution. We want to test the hypothesis \(H_0 : \Sigma = \Sigma_0\), where \(\Sigma_0\) is a specified positive definite matrix.

Suppose \(\mu\) is unknown, and let \(S = (n-1)^{-1}X'HX\) be the sample covariance matrix. The union intersection test uses the largest eigenvalue of \(\Sigma_0^{-1}S\), denoted by \(\hat{\lambda}_1(\Sigma_0^{-1}S)\), as the test statistic [23, p.130]. Observe that \(\hat{\lambda}_1(\Sigma_0^{-1}S) = \hat{\lambda}_1(\Sigma_0^{-1/2}SS_0^{-1/2})\). Under \(H_0\), \((n-1)\Sigma_0^{-1/2}SS_0^{-1/2} \sim W_p(I, n-1)\). So, our result is available for \((n-1)\hat{\lambda}_1(\Sigma_0^{-1}S)\).

**Singular value decomposition.** For \(X\) a real \(n \times p\) matrix, there exist orthogonal matrices \(U(n \times n)\) and \(V(p \times p)\), such that \(X = UDV^T\),

where \(D = \text{diag}(d_1, \cdots, d_{n,p}) \in \mathbb{R}^{n \times p}\), and \(d_1 \geq \cdots \geq d_{n,p} \geq 0\). This representation is called the singular value decomposition of \(X\) [13, Theorem 7.3.5], with \(d_i\) the \(i\)-th singular value of \(X\). Theorem [1] then provides an accurate distributional approximation for \(d_i^2\) when the entries of \(X\) are independent standard normal random variables.

### 2.4 The Score Data Example

We consider now the score data example extracted from [23]. The data set consists of the scores of 88 students on five subjects (mechanics, vectors, algebra, analysis and statistics). Taking account of centering, we have \(n = 87\) and \(p = 5\). One might expect that there are several common factors that determine the students’ performance on the tests. Moreover, one might assume that the joint effects of the common factors are observed in isotropic noises, in which case the covariance structure of the scores (after proper diagonalization) follows a spiked model \(\Sigma = \tau^2 \Sigma_m\), where \(\tau^2 > 0\) and \(\Sigma_m = \text{diag}(\hat{\lambda}_1, \cdots, \hat{\lambda}_m, 1, \cdots, 1)\) and \(0 \leq m \leq 4\). (Note that the model \(\Sigma = \tau^2 \Sigma_5\) is the saturated model and is indistinguishable from \(\Sigma = \tau^2 \Sigma_5\).) To determine \(m\), we are led to test a nested sequence of hypotheses \(H_k : \Sigma = \tau^2 \Sigma_m\) with some \(m \leq k\), for \(0 \leq k \leq 3\).

To compute the \(p\)-value of testing \(H_k\), we could (i) estimate \(\tau^2\) by \(\hat{\tau}_p^2\) as the mean of the \(p-k\) smallest sample eigenvalues; (ii) construct the test statistic as \(T_k = (n\hat{\lambda}_{k+1}/\hat{\sigma}_{p-k}^2 - \mu_{n,p-k})/\sigma_{n,p-k}\); (iii) report \(F_1(T_k)\) as the approximate conservative \(p\)-value. Step (iii) is justified as follows. Let \(L(\lambda_j|n,p,\Sigma)\) denote the law of the \(j\)-th largest sample eigenvalue of a \(W_p(n, \Sigma)\) matrix. By the interlacing properties of the eigenvalues [13, Theorem 7.3.9] (see also [15, Proposition 1.2]), \(L(\lambda_1|n,p-m, I_{p-m})\) could be used to compute conservative \(p\)-value for the null distribution \(L(\lambda_{k+1}|n,p, \Sigma_m)\) for all \(k \geq m\), which is further approximated by \(F_1\). We summarize the values of \(T_k\) and the corresponding \(p\)-values in Table [3].

From Table [3], we could see a noticeable difference between the values of \(T_k\) and the corresponding \(p\)-values by using different rescaling constants. The \(p\)-values obtained from the new constants are typically smaller than those from the old constants. Noting that the \(p\)-values are

already conservative, the new constants (4) prevent further unnecessary conservativeness that would otherwise be caused by the old constants in this example.

2.5 Discussion

We discuss below two issues related to our results.

Log transform. One notable difference between Theorems 1 and 2 is the logarithmic transformation of the smallest eigenvalue before scaling.

Indeed, for the largest eigenvalue, a similar $O(N^{-2/3})$ convergence rate can be obtained for the distribution of $(\log \lambda_1 - \nu_{n,p})/\tau_{n,p}$, with $\nu_{n,p} = \log(\mu_{n,p})$ and $\tau_{n,p} = \sigma_{n,p}/\mu_{n,p}$. However, when $n$ or $p$ is small, its numerical results are not as good as those obtained from direct scaling. In comparison, for the smallest eigenvalue, the transform yields substantial numerical improvement. Therefore, we recommend the log transform for the smallest eigenvalue.

As no theoretical analysis justifying the choice of the transform is currently available, we attempt some heuristics in the following. First, observe that sample covariance matrices are positive semi-definite. So, for $\lambda_p$, the hard lower bound at 0 truncates the left tail of its density function on any linear scale, and hence obstructs the asymptotic approximation by $G_1$ which is supported on the whole real line. However, by a map $x \mapsto \log x$, we maps the support to the whole real line and avoids the ‘hard edge’ effect. The largest eigenvalue does not necessarily benefit from this transform, for it is on the ‘soft edge’, i.e., the right edge of the covariance matrix spectrum, which does not have a deterministic upper bound. Such heuristics are supported by related studies on Gaussian Wigner matrices [17] and $F$-matrices [16].

Software. There have been works on the numerical evaluation of the Tracy-Widom distributions [4, 8, 5] and the exact finite $n \times p$ distributions of the extreme eigenvalues [19, 20]. In addition, the author and colleagues have developed an R package RMTstat [18] that is intended to provide an interface for using the Tracy-Widom approximation in multivariate statistical analysis.

3 The Largest Eigenvalue

This section is devoted to the proof of Theorem 1. We use the operator norm convergence framework developed in [35], for the joint eigenvalue distribution of white Wishart matrices is essentially the same as the Laguerre orthogonal ensemble in Random Matrix Theory (RMT).

In the proof, we first give the determinantal representations for the finite and limiting distribution functions and work out explicit formulas for related kernels, in which Widom’s formula (12) plays the central role. Then, a Lipschitz type inequality shows that the difference in determinants is bounded by the difference in kernels. The representation of the finite sample kernel involves
Henceforth, we identify the LOE(\(\alpha\)) of quantities on them. A decomposition of the kernel difference then enables us to transfer bounds on convergence of Laguerre polynomials to Airy function to bounds on the kernel difference, and eventually to bounds on the difference of the probabilities.

### 3.1 Determinantal Laws

Following RMT notational convention, we replace the dimension parameter \(p\) of a white Wishart matrix \(A\) by \(N\), and use \(x_i\) instead of \(\lambda_i\) to denote its eigenvalues. Henceforth, we assume that \(N\) is even, \(n = n(N) \geq N + 1\) and \(n/N \to \gamma \in [1, \infty)\) as \(N \to \infty\). The cases \(\gamma \in (0,1]\) are easily obtained by interchanging \(n\) and \(N\).

In the RMT literature, for an integer \(N \geq 2\) and any \(\alpha > -1\), the Laguerre orthogonal ensemble with parameters \(N\) and \(\alpha\), denoted by \(\text{LOE}(N,\alpha)\), refer to joint eigenvalue density

\[
\tilde{p}_N(x_1, \cdots, x_N) = \frac{1}{Z_{N,\alpha}} \prod_{1 \leq j < k \leq N} (x_j - x_k) \prod_{j=1}^N x_j^\alpha e^{-x_j/2},
\]

where \(x_1 \geq \cdots \geq x_N \geq 0\). If further \(\alpha\) is a non-negative integer, \(\text{(7)}\) matches the density function of ordered eigenvalues \(x_1 \geq \cdots \geq x_N \geq 0\) from a white Wishart matrix \(A \sim W_N(I, n)\), with

\[
\alpha = n - N - 1.
\]

Henceforth, we identify the \(\text{LOE}(N,\alpha)\) model with eigenvalues of \(A \sim W_N(I, n)\) by \(\text{(8)}\). Thinking of \(\alpha\) and \(n\) as functions of \(N\), in what follows, we sometimes drop explicit dependence of certain quantities on them.

For \(\text{LOE}(N,\alpha)\), [34, Section 9] derived the following determinantal formula

\[
\tilde{F}_{N,1}(x') = P\{x_1 \leq x'\} = \sqrt{\det(I - K_N\chi)}.
\]

Here \(\chi = 1_{x>x'}\) and \(K_N\) is an operator with \(2 \times 2\) matrix kernel

\[
K_N(x,y) = (LS_{N,1})(x,y) + K^\varepsilon(x,y),
\]

where

\[
L = \begin{pmatrix}
I & -\partial_2 \\
\varepsilon_1 & T
\end{pmatrix}, \quad K^\varepsilon = \begin{pmatrix}
0 & 0 \\
-\varepsilon(x-y) & 0
\end{pmatrix}.
\]

In \(L\), \(\partial_2\) is the differential operator with respect to the second argument, \(\varepsilon_1\) is the convolution operator acting on the first argument with the kernel \(\varepsilon(x-y) = \frac{1}{2}\text{sgn}(x-y)\) and \(TK(x,y) = K(y,x)\) for any kernel \(K\).

To give explicit formula for \(S_{N,1}\), introduce the generalized Laguerre polynomials \(\{L_k^\alpha\}_{k=0}^\infty\) [31, Chapter V], which are orthogonal on \([0,\infty)\) with weight function \(x^\alpha e^{-x}\). The normalized and weighted versions of them become

\[
\phi_k(x;\alpha) = h_k^{-1/2}x^{\alpha/2}e^{-x/2}L_k^\alpha(x), \quad k = 0, \cdots,
\]

with \(h_k = \int_0^\infty L_k^\alpha(x)^2x^{\alpha/2}e^{-x}dx = (k + \alpha)!/k!\). Widom [36] derived a formula for \(S_{N,1}\), which can be rewritten in a form more convenient to us [1, Eq.(4.3)] as

\[
S_{N,1}(x,y) = S_{N,2}(x,y) + \frac{N!}{4\Gamma(N+\alpha)}x^{\alpha/2}e^{-x/2}\left[\frac{d}{dx}L_N^\alpha(x)\right] \\
\times \int_0^\infty \text{sgn}(y-z)z^{\alpha/2-1}e^{-z/2}[L_N^\alpha(z) - L_{N-1}^\alpha(z)]dz,
\]

\[9\]
where \( S_{N,2} \) is the unitary correlation kernel
\[
S_{N,2}(x, y) = \sum_{k=0}^{N-1} \phi_k(x; \alpha) \phi_k(y; \alpha).
\]

Let \( a_N = \sqrt{N(N + \alpha)} \), and define as in [10] Section 2 functions
\[
\phi(x; \alpha) = (-1)^N \sqrt{\frac{a_N}{2}} \phi_N(x; \alpha - 1)x^{-1/2}1_{x \geq 0},
\]
\[
\psi(x; \alpha) = (-1)^{N-1} \sqrt{\frac{a_N}{2}} \phi_{N-1}(x; \alpha + 1)x^{-1/2}1_{x \geq 0}.
\]

Write \( a \circ b \) for the operator with kernel \((a \circ b)(x, y) = \int_0^\infty a(x + z)b(y + z)dz\). Then \( S_{N,2} \) has the integral representation [15] [10]
\[
S_{N,2}(x, y) = \int_0^\infty \phi(x + z)\psi(y + z) + \psi(x + z)\phi(y + z)dz = (\phi \circ \psi + \psi \circ \phi)(x, y).
\]

By [31] Eq.(5.1.13), (5.1.14)], the second term on the right side of (12) equals
\[
-\frac{N!}{4\Gamma(N + \alpha)}x^{\alpha/2}e^{-x/2}L_{N-1}^{\alpha+1}(x)\int_0^\infty \text{sgn}(y-z)z^{\alpha/2-1}e^{-z/2}L_N^{\alpha-1}(z)dz = \psi(x)(\varepsilon\phi)(y).
\]

Hence, we obtain
\[
S_{N,1}(x, y) = S_{N,2}(x, y) + \psi(x)(\varepsilon\phi)(y)
\]
with \( S_{N,2}(x, y) \) given in [14]. Together with [9] and [10], this gives the determinantal representation of the finite sample distribution on the original scale.

The Tracy-Widom limit has a corresponding determinantal representation [35]
\[
F_1(s') = \sqrt{\det(I - K_{GOE})},
\]
where \( f = 1_{s > s'} \) and the operator \( K_{GOE} \) has the matrix kernel
\[
K_{GOE}(s, t) = \begin{pmatrix} S(s, t) & SD(s, t) \\ IS(s, t) & S(t, s) \end{pmatrix} + K^\varepsilon(s, t).
\]

Introduce the right-tail integration operator \( \tilde{\varepsilon} \) as in [16], where \((\tilde{\varepsilon}g)(s) = \int_s^\infty g(u)du\) and for kernel \( K(s, t) \), \((\tilde{\varepsilon}K)(s, t) = \int_s^\infty K(u, t)du\). Also write \( a \otimes b \) for rank one operator with kernel \((a \otimes b)(s, t) = a(s)b(t)\). Then the entries of \( K_{GOE} \) are
\[
S(s, t) = (A_1 - \frac{1}{2}\varepsilon \otimes \varepsilon A_1)(s, t) + \frac{1}{2}\varepsilon A_1(s),
\]
\[
SD(s, t) = -\partial_2(S_A(s, t) - \frac{1}{2}\varepsilon \otimes \varepsilon A_1)(s, t),
\]
\[
IS(s, t) = -\tilde{\varepsilon}(S_A - \frac{1}{2}\varepsilon \otimes \varepsilon A_1)(s, t) - \frac{1}{2}(\varepsilon A_1)(s) + \frac{1}{2}(\varepsilon A_1)(t).
\]

Here \( S_A(s, t) = (A_1 \otimes A_1)(s, t) \) is the Airy kernel, and \( A_1(\cdot) \) is the Airy function [26] p.53, Eq.(8.01)].

Let \( G = \frac{1}{\sqrt{2}}A_1 \), and define matrix operators
\[
\tilde{L} = \begin{pmatrix} I & -\partial_2 \\ -\tilde{\varepsilon} & T \end{pmatrix}, \quad L_1 = \begin{pmatrix} I & 0 \\ -\tilde{\varepsilon} & 0 \end{pmatrix}, \quad L_2 = \begin{pmatrix} 0 & 0 \\ \tilde{\varepsilon} & I \end{pmatrix}.
\]

We can write \( K_{GOE} \) in a compact form as
\[
K_{GOE} = \tilde{L}(S_A - G \otimes \varepsilon G) + L_1(G \otimes \frac{1}{\sqrt{2}}) + L_2(\frac{1}{\sqrt{2}} \otimes G) + K^\varepsilon.
\]
3.2 Rescaling the Finite Sample Kernel

Under the current RMT notation, the rescaling constants \([4]\) are translated to

\[
\mu_{n,N} = \left(\sqrt{m} + \sqrt{N}\right)^2, \quad \sigma_{n,N} = \left(\frac{1}{\sqrt{m}} + \frac{1}{\sqrt{N}}\right)^{1/3}.
\]  

(19)

Introduce the linear transformation \(\tau(s) = \mu_{n,N} + s\sigma_{n,N}\), and let \(F_{N,1}(\cdot) = \tilde{F}_{N,1}(\tau(\cdot))\) be the distribution function of \(\tau^{-1}(x_1)\), i.e. the largest eigenvalue of \(A \sim W_N(I,n)\), rescaled by (19).

Define the rescaled kernel \(\tilde{K}_\tau\) as

\[
\tilde{K}_\tau(s,t) = \sqrt{\tau'(s)\tau'(t)} K_N(\tau(s), \tau(t)) = \sigma_{n,N} K_N(\tau(s), \tau(t)).
\]  

(20)

Since \(K_N\) and \(\tilde{K}_\tau\) share the spectrum, \(F_{N,1}(s') = \sqrt{\text{det}(I - K_{\tau}f)}\).

To work out a representation for \(\tilde{K}_\tau\), apply the \(\tau\)-scaling to \(\phi, \psi\) and \(S_{N,2}\) to define

\[
\phi_\tau(s) = \sigma_{n,N} \phi(\mu_{n,N} + s\sigma_{n,N}), \quad \psi_\tau(s) = \sigma_{n,N} \psi(\mu_{n,N} + s\sigma_{n,N})
\]  

and

\[
S_\tau(s,t) = \sigma_{n,N} S_{N,2}(\mu_{n,N} + s\sigma_{n,N}, \mu_{n,N} + t\sigma_{n,N}) = (\phi_\tau \circ \psi_\tau + \psi_\tau \circ \phi_\tau)(s,t).
\]  

(21)

Then, we obtain from (15) that

\[
S^R_\tau(s,t) = \sqrt{\tau'(s)\tau'(t)} S_{N,1}(\tau(s), \tau(t)) = S_\tau(s,t) + \psi_\tau(s)(\varepsilon \phi_\tau)(t).
\]  

(23)

This, together with (10) and (20), leads to

\[
\tilde{K}_\tau(s,t) = \left(\frac{I}{\sigma_{n,N} \cdot \varepsilon_1} - \sigma_{n,N}^{-1} \cdot \partial_2\right) S^R_\tau(s,t) + \sigma_{n,N} K^\varepsilon(s,t).
\]

Observe that \(\text{det}(I - \tilde{K}_\tau f)\) remains unchanged if we divide the lower left entry by \(\sigma_{n,N}\) and multiply the upper right entry by \(\sigma_{n,N}\). Thus, we obtain

\[
F_{N,1}(s') = \sqrt{\text{det}(I - \tilde{K}_\tau f)},
\]  

(24)

with

\[
K_\tau(s,t) = (LS^R_\tau)(s,t) + K^\varepsilon(s,t).
\]  

(25)

To match the representation (18) of \(K_{GOE}\), and to facilitate later arguments, it is helpful to rewrite \(LS^R_\tau\), and hence \(K_\tau\), using \(\varepsilon\). To this end, observe that \(\int \psi_\tau = 0\), and let

\[
\beta_\varepsilon = \frac{1}{2} \int_{-\infty}^{\infty} \phi_\tau(s) ds.
\]  

(26)

By the identity \((\varepsilon g)(s) = \frac{1}{2} \int g - (\bar{\varepsilon} g)(s)\), we obtain \(\varepsilon \phi_\tau = \beta_\varepsilon - \bar{\varepsilon} \phi_\tau\) and \(\varepsilon \psi_\tau = -\bar{\varepsilon} \psi_\tau\), and so

\[
LS^R_\tau = L(S_\tau - \psi_\tau \odot \bar{\varepsilon} \phi_\tau) + \beta_\varepsilon L(\psi_\tau \odot 1).
\]

Now \(L = \tilde{L} + E\) with \(E = \begin{pmatrix} 0 & 0 \\ \varepsilon_1 + \bar{\varepsilon}_1 & 0 \end{pmatrix}\). Since \(2(\varepsilon_1 + \bar{\varepsilon}_1)\) equals integration over \(\mathbb{R}\) in the first argument and \(\int \psi_\tau = 0\), we obtain

\[
LS^R_\tau = \tilde{L}(S_\tau - \psi_\tau \odot \bar{\varepsilon} \phi_\tau) + ES_\tau + \beta_\varepsilon \tilde{L}(\psi_\tau \odot 1) \\
= \tilde{L}(S_\tau - \psi_\tau \odot \bar{\varepsilon} \phi_\tau) + \beta_\varepsilon L_1(\psi_\tau \odot 1) + \beta_\varepsilon L_2(1 \odot \psi_\tau).
\]

The second equality holds, for \((ES_\tau)_{21} = \frac{1}{2} \int_{-\infty}^{\infty} S_\tau(u,t) dt = \beta_\varepsilon \int_0^{\infty} \psi_\tau(t + z) dz = \beta_\varepsilon (\bar{\varepsilon} \psi_\tau)(t)\).

Finally, this gives \(K_\tau\) a similar decomposition to that of \(K_{GOE}\)

\[
K_\tau = \tilde{L}(S_\tau - \psi_\tau \odot \bar{\varepsilon} \phi_\tau) + L_1(\psi_\tau \odot \beta_\varepsilon) + L_2(\beta_\varepsilon \odot \psi_\tau) + K^\varepsilon.
\]  

(27)
3.3 Generalized Fredholm Determinants

For any fixed $s_0 \in \mathbb{R}$, we are interested in the convergence rate of $F_{N,1}(s')$ to $F_1(s')$ for all $s' \geq s_0$. In what follows, we show that this relies on the operator convergence of $K_\tau$ to $K_{GOE}$.

First, we note that the determinants in [9], [16] and [24] are not the usual Fredholm determinants as the $\varepsilon$ term on the lower-left position of the matrix kernels is not of trace class. Tracy and Widom [35] first observed the problem, and proposed a solution by introducing weighted Hilbert spaces and regularized 2-determinants, which we adopt here.

Consider the determinant in (9). Let $\tilde{\rho}$ be a weight function such that (1) its reciprocal $\tilde{\rho}^{-1} \in L^1[0,\infty)$; and (2) $S_{N,1}^\tau \in L^2((x',\infty);\tilde{\rho}) \cap L^2((x',\infty);\tilde{\rho}^{-1})$. Then $\varepsilon$: $L^2((x',\infty);\tilde{\rho}) \rightarrow L^2((x',\infty);\tilde{\rho}^{-1})$ is Hilbert-Schmidt, and $K_N$ can be regarded as a $2 \times 2$ matrix kernel on the space $L^2((x',\infty);\tilde{\rho}) \oplus L^2((x',\infty);\tilde{\rho}^{-1})$. In addition, by the second condition on $\tilde{\rho}$, the diagonal entries of $K_N$ are trace class on $L^2((x',\infty);\tilde{\rho})$ and $L^2((x',\infty);\tilde{\rho}^{-1})$ respectively.

For a Hilbert-Schmidt operator $T$ with eigenvalues $\mu_k$, its regularized 2-determinant [12] is defined as $\det_2(I - T) \equiv \prod_k (1 - \mu_k)e^{\mu_k}$. If further the diagonal elements of $T$ are trace class, then we define generalized Fredholm determinant for $T$ as

$$\det(I - T) = \det_2(I - T) \exp(-\text{tr}T).$$

(28)

As remarked in [35], the definition (28) is independent of the choice of $\tilde{\rho}$ and allows the derivation in [34] that yields [9], [10] and eventually [15].

Change the domain to $(s',\infty)$ with $s' = \tau^{-1}(x')$ and the weight function to $\rho = \tilde{\rho} \circ \tau$, and abbreviate $L^2((s',\infty);\rho)$ as $L^2(\rho)$ for any suitable $\rho$. Then, $K_\tau$ and $K_{GOE}$ are members of the operator class $\mathcal{A}$ of $2 \times 2$ Hilbert-Schmidt operator matrices on $L^2(\rho) \oplus L^2(\rho^{-1})$ with trace class diagonal entries. Definition (28) and previous derivations in Section 3.2 remain valid.

In order to make the later argument more explicit, it is convenient to make a specific choice of the weight function $\rho$. In particular, on the $s$-scale, we choose

$$\rho(s) = 1 + \exp(\frac{|s|}{s_0}).$$

(29)

This implies that on the $x$-scale, we specify the weight function $\tilde{\rho} = \rho \circ (\tau^{-1})$ as

$$\tilde{\rho}(x) = 1 + \exp(\frac{|x - \mu_{n,N}|}{\sigma_{n,N}}).$$

It is straightforward to verify that the required conditions are all satisfied.

With rigorous definition of determinants, we now relate the convergence of $F_{N,1}$ to $F_1$ to that of $K_\tau$ to $K_{GOE}$. First of all, simple manipulation leads to

$$|F_{N,1}(s') - F_1(s')| \leq \frac{|F_{N,1}^2(s') - F_1^2(s')|}{F_1(s_0)} = \frac{1}{F_1(s_0)}|\det(I - K_\tau) - \det(I - K_{GOE})|. \quad (30)$$

To bound the difference between the determinants, we have the following Lipschitz-type inequality. Here and after, $\| \cdot \|_1$ and $\| \cdot \|_2$ denote trace class norm and Hilbert-Schmidt norm respectively.

Proposition 1. Let $A, B \in \mathcal{A}$, and $\det(I - A)$, $\det(I - B)$ defined as in (28). If $\sum_{i=1}^2 \|A_{ii} - B_{ii}\|_1 + \sum_{i \neq j} \|A_{ij} - B_{ij}\|_2 \leq 1/2$, then

$$|\det(I - A) - \det(I - B)| \leq M(B)\left(\sum_{i=1}^2 \|A_{ii} - B_{ii}\|_1 + \sum_{i \neq j} \|A_{ij} - B_{ij}\|_2\right), \quad \text{(31)}$$

where $M(B) = 2 \|\det(I - B)\| + 2 \exp(2(1 + \|B\|_2)^2) + \sum_i \|B_{ii}\|_1$.

---

2See, for example, [21] for an introduction to the Fredholm determinant.
Proof. [16] Proposition 3] established a similar bound to (31), but with $M(B)$ replaced by

$$C(A, B) = |e^{-\text{tr}A}| \exp\left[\frac{1}{2}(1 + \|A\|_2 + \|B\|_2)^2\right] + |\det_2(I - B)|\frac{|e^{-\text{tr}A} - e^{-\text{tr}B}|}{|\text{tr}A - \text{tr}B|}.$$ 

We now bound $C(A, B)$ by the above claimed constant $M(B)$.

Observe that for $|x| \leq 1/2$, $|e^x - 1| \leq 2|x|$. Therefore, when \( \sum_{i=1}^{2} \|A_{ii} - B_{ii}\|_1 + \sum_{i \neq j} \|A_{ij} - B_{ij}\|_2 \leq 1/2 \), we have $|\text{tr}A - \text{tr}B| \leq \sum_{i=1}^{2} \|A_{ii} - B_{ii}\|_1 \leq 1/2$, which in turn implies $|e^{-\text{tr}A} - e^{-\text{tr}B}| \leq 2|\text{tr}A - \text{tr}B|$. Hence, for the terms in $C(A, B)$, we have

$$|e^{-\text{tr}A}| \leq |e^{-\text{tr}B} - e^{-\text{tr}A}| + |e^{-\text{tr}B}| \leq |e^{-\text{tr}B}| (2|\text{tr}A - \text{tr}B| + 1)$$

and

$$|\det_2(I - B)|\frac{|e^{-\text{tr}A} - e^{-\text{tr}B}|}{|\text{tr}A - \text{tr}B|} \leq 2|\det_2(I - B)||e^{-\text{tr}B}| = 2|\det(I - B)|.$$

Moreover, we observe that

\[
1 + \|A\|_2 + \|B\|_2 \leq 1 + 2\|B\|_2 + \|A - B\|_2
\]

\[
\leq 1 + 2\|B\|_2 + \sum_{i=1}^{2} \|A_{ii} - B_{ii}\|_1 + \sum_{i \neq j} \|A_{ij} - B_{ij}\|_2
\]

\[
\leq 2 + 2\|B\|_2,
\]

Plugging all these bounds into $C(A, B)$, we obtain the claimed form of $M(B)$.

\[ \square \]

Remark. Proposition [1] refines [16] Proposition 3] by having the leading constant $M(B)$ of the bound depend only on $B$, which is important for deriving properties of the $C(s_0)$ function later.

### 3.4 Decomposition of $K_{\tau} - K_{\text{GOE}}$

By Proposition [1] to prove Theorem [1] is essentially to control the entrywise convergence rate of $K_{\tau}$ to $K_{\text{GOE}}$. To this end, we construct a telescopic decomposition of $K_{\tau} - K_{\text{GOE}}$ into sums of simpler matrix kernels whose entries are more tractable.

To explain the intuition behind the decomposition, we introduce constants $\tilde{\mu}_{n,N}$ and $\tilde{\sigma}_{n,N}$ as

\[
\tilde{\mu}_{n,N} = \left(\sqrt{n_+} + \sqrt{N_+}\right)^2, \quad \tilde{\sigma}_{n,N} = \left(\sqrt{n_+} + \sqrt{N_+}\right)\left(\frac{1}{\sqrt{n_+}} + \frac{1}{\sqrt{N_+}}\right)^{1/3}.
\]

In [10], it was shown that $(\mu_{n,N}, \sigma_{n,N}) = (\tilde{\mu}_{n-1,N-1}, \tilde{\sigma}_{n-1,N-1})$ is ‘optimal’ for $\psi_{\tau}$ in the sense that $|\psi_{\tau} - G| = O(N^{-2/3})$, but suboptimal for $\phi_{\tau}$ as $|\phi_{\tau} - G| = O(N^{-1/3})$. However, later in Proposition [2] we will show that $|\phi_{\tau} - G - \Delta_N G'| = O(N^{-2/3})$ for

\[
\Delta_N = \frac{\tilde{\mu}_{n-1,N-1} - \tilde{\mu}_{n-2,N}}{\tilde{\sigma}_{n-2,N}} = O(N^{-1/3}).
\]

[For a proof, see [A.1].] These bounds suggest that, in the decomposition, we align $\psi_{\tau}$ with $G$, and $\phi_{\tau}$ with $G + \Delta_N G'$. Let $G_N = G + \Delta_N G'$ and $S_{A_N} = G \circ G_N + G_N \circ G$. We obtain

\[
S_{A_N} - G \circ \tilde{e} G_N = S_A - G \circ \tilde{e} G,
\]

13
Lemma 2 that Lemma 1. Fix the bounds for detail later in Section 5. Liouville-Green analysis on the solution of certain differential equation and will be discussed in G and D obtain that where \( \sqrt{2} \) Ai and \( G \) and \( \mathcal{D} \) be defined as in \( \psi \) and \( \psi' \) and \( \psi'' \), such that when \( N \geq N_0(s_0, \gamma) \), for all \( s \geq s_0 \),

\[
|\psi(s)|, \quad |\psi'(s)| \leq C(s_0) \exp(-s), \tag{35}
\]

\[
|\phi(s)|, \quad |\phi'(s)| \leq C(s_0) \exp(-s), \tag{36}
\]

\[
|\psi(s) - G(s)|, \quad |\psi'(s) - G'(s)| \leq C(s_0) N^{-2/3} \exp(-s), \tag{37}
\]

\[
|\phi(s) - G_N(s)|, \quad |\phi'(s) - G'_N(s)| \leq C(s_0) N^{-2/3} \exp(-s), \tag{38}
\]

where \( C(\cdot) \) is continuous and non-increasing.

Integrating these bounds over \([s, \infty)\), we know that they remain valid if we replace \( \psi, \phi, G \) and \( G_N \) with \( \varepsilon \psi, \varepsilon \phi, \varepsilon G \) and \( \varepsilon G_N \) on the left sides. The proof of Proposition 2 involves careful Liouville-Green analysis on the solution of certain differential equation and will be discussed in detail later in Section 5.

On the other hand, for \( G \) and \( G_N \), we have the following bounds from [26, p.394]. Note that the bounds for \( G_N \) and \( G'_N \) do not depend on \( N \), for \( \Delta \) is uniformly bounded.

Lemma 1. Fix \( \beta > 0 \) and \( k \geq 0 \). Then, for all \( s \geq s_0 \),

\[
|s^k G(s)|, \quad |s^k G_N(s)|, \quad |s^k G'(s)|, \quad |s^k G'_N(s)| \leq C(s_0) e^{-\beta s},
\]

where \( C(s_0) \) is continuous and non-increasing.

For a proof of the lemma, see [22]. Integrating the bounds for \(|G|\) and \(|G_N|\) over \([s, \infty)\), we obtain that \(|\varepsilon G|\) and \(|\varepsilon G_N|\) are also bounded by \( C(s_0) e^{-\beta s} \).

For later operator convergence argument, we will need simple bounds for certain norms of operator \( D : L^2(\rho_1) \to L^2(\rho_2) \) with kernel \( D(u, v) = \alpha(u) \beta(v)(a \circ b)(u, v) \), where \( \{\rho_1, \rho_2\} \subset \{\rho, \rho^{-1}\} \) with \( \rho \) given in [29]. In particular, we have

Lemma 2 ([16]). Let \( D : L^2(\rho_1) \to L^2(\rho_2) \) have kernel \( D(u, v) = \alpha(u) \beta(v)(a \circ b)(u, v) \). Suppose that \( \{\rho_1, \rho_2\} \subset \{\rho, \rho^{-1}\} \), and that for \( u \geq s' \),

\[
|\alpha(u)| \leq a_0 e^{a_1 u}, \quad |\beta(u)| \leq b_0 e^{b_1 u}, \quad |a(u)| \leq a_0 e^{-a_1 u}, \quad |b(u)| \leq b_0 e^{-b_1 u}, \tag{39}
\]

with \( a_1 - a_1, b_1 - \beta_1 \geq 1 \). Then the Hilbert-Schmidt norm satisfies

\[
\|D\|_2 \leq C \frac{a_0 b_0}{a_1 + b_1} \exp \left[-(a_1 + b_1 - a_1 - b_1)s' + |s'| \right], \tag{40}
\]

where \( C = C(a_1, a_1, b_1, \beta_1) \). If \( \rho_1 = \rho_2 \), the trace norm \( \|D\|_1 \) satisfies the same bound.
3.6 Operator Convergence: Proof of Theorem 1

Abbreviate the terms in the decomposition (34) as

\[ K_\tau - K_{GOE} = \delta^R + \delta^F_0 + \delta^F_1 + \delta^F_2. \]

We work out below entrywise bounds for each of these \( \delta \) terms and then apply Proposition [1] to complete the proof of Theorem [1] In what follows, we use the abbreviation \( D^{(k)} f, k = -1, 0, 1 \) to denote \( \tilde{e} f, f \) and \( f' \) respectively. Moreover, the unspecified norm \( \| \cdot \| \) denotes Hilbert-Schmidt norm \( \| \cdot \|_2 \) for off-diagonal entries and trace class norm \( \| \cdot \|_1 \) for diagonal ones.

**\( \delta^R \) term.** Recall that \( \delta^R = \tilde{L}(S_\tau - S_{\Lambda_N}) \) with \( S_\tau = \phi_\tau \circ \psi_\tau + \psi_\tau \circ \phi_\tau \) and \( S_{\Lambda_N} = G_N \circ G + G \circ G_N \). Regardless of the signs, we have the following unified expression for the entries of \( \delta^R \):

\[ (\delta^R)_{ij} = D^{(k)}(\phi_\tau - G_N) \circ D^{(l)}\psi_\tau + D^{(k)}G_N \circ D^{(l)}(\psi_\tau - G) + D^{(k)}(\psi_\tau - G) \circ D^{(l)}\phi_\tau + D^{(k)}G \circ D^{(l)}(\phi_\tau - G_N), \]

for \( i, j \in \{1, 2\}, k \in \{-1, 0, 1\} \) and \( l \in \{0, 1\} \). By Proposition [2] and Lemma [1], we find that for any of the four terms in (41), the condition (39) is satisfied with \( \alpha_0 = \beta_0 = 1, \alpha_1 = \beta_1 = 0, a_1 = b_1 = 1 \) and \( \{a_0, b_0\} = \{C(s_0), C(s_0)N^{-2/3}\} \). So Lemma [2] implies

\[ \| (\delta^R)_{ij} \| \leq C(s_0)N^{-2/3} \exp(-2s' + |s'|). \]

By a simple triangle inequality, we can choose \( C(s_0) \) in the last display as the sum of products of continuous and non-increasing functions, which can be seen from the term \( (a_0\beta_0a_0b_0)/(a_1 + b_1) \) in (40). Moreover, the term \( C \) in (40) is a universal constant for fixed \( a_1, \alpha_1, b_1 \) and \( \beta_1 \) here. Hence, the final \( C(s_0) \) function remains continuous and non-increasing.

**Finite rank terms.** For a rank one operator \( a \otimes b : L^2(\rho_1) \to L^2(\rho_2) \) with kernel \( a(s)b(t) \), its norm is

\[ \|a \otimes b\| = \|a\|_{2,\rho_2}\|b\|_{2,\rho_1}. \]

Here, the norm can be either trace class or Hilbert-Schmidt, for the two agree for rank one operators. In addition, for any \( \varrho \), \( \|a\|_{2,\varrho}^2 = \int_{s'} \|a(s)\|^2\varrho(s)ds \). Now consider matrices of rank one operators on \( L^2(\rho) \otimes L^2(\rho^{-1}). \) Write \( \| \cdot \|_+ \) and \( \| \cdot \|_- \) for \( \| \cdot \|_2, \rho \) and \( \| \cdot \|_{2,\rho^{-1}} \) respectively. [16] Eq.(213] gives the following bound

\[ \left( \begin{array}{cc} a_{11} \otimes b_{11} & a_{12} \otimes b_{12} \\ a_{21} \otimes b_{21} & a_{22} \otimes b_{22} \end{array} \right) \leq \left( \begin{array}{cc} a_{11} & b_{11} \\ a_{21} & b_{21} \end{array} \right) \leq \left( \begin{array}{cc} a_{11} & a_{12} \\ a_{21} & a_{22} \end{array} \right). \]

First consider \( \delta^F_0 \). We reorganize it as

\[ \delta^F_0 = -\tilde{L}(\psi_\tau \otimes \tilde{e}_\psi_\tau - G \otimes \tilde{e}G_N) = -\tilde{L}[\psi_\tau \otimes \tilde{e}(\phi_\tau - G_N) + (\psi_\tau - G) \otimes \tilde{e}G_N] = \delta^F_{0,1} + \delta^F_{0,2}. \]

The entries of \( \delta^F_{0,i}, i = 1, 2, \) are all of the form \( a \otimes b, \) with \( a \) and \( b \) chosen from \( D^{(k)}(\psi_\tau), D^{(k)}(\phi_\tau - G_N), D^{(k)}(\psi_\tau - G) \) and \( D^{(k)}G_N, \) for \( k \in \{-1, 0, 1\} \).

Observe that for \( \eta \geq 2, \) we have

\[ \int_{s'}^{\infty} \exp(-\eta s)\rho_{s'}^+1(s)ds \leq \frac{4}{\eta - 1} \exp(-\eta s' \pm |s'|) \leq \frac{8}{\eta} \exp(-\eta s' + |s'|). \]
Together with Proposition\textsuperscript{2} and Lemma\textsuperscript{1} this implies
\[
\|D^{(k)}\psi_r\|_\pm^2, \|D^{(k)}G_N\|_\pm^2 \leq C(s_0) \exp(-2s' + |s'|),
\]
\[
\|D^{(k)}(\psi_r - G)\|_\pm^2, \|D^{(k)}(\phi_r - G_N)\|_\pm^2 \leq C(s_0)N^{-4/3} \exp(-2s' + |s'|).
\]

These bounds, together with the triangle inequality and (45), yield
\[
\|\delta_0^F\|_1 \leq \|\psi_r \otimes \beta_N - G\|_1 + \|\psi_r - G\|_1 \leq \|\psi_r\|_1 + \|\beta_N - G\|_1 \leq C(s_0)N^{-2/3} \exp(-2s' + |s'|).
\]

Similarly, we obtain the bounds for the other entries. In summary, we have
\[
\|\delta_0^F\| \leq C(s_0)N^{-2/3} \exp(-2s' + |s'|), \quad \text{for} \quad k = -1, 0.
\] (45)

Switch to $\delta_1^F$ and $\delta_2^F$. Recall that $\delta_1^F = L_1(\psi_r \otimes \beta_N - G \otimes \sqrt{2})$ and $\delta_2^F = L_2(\beta_N \otimes \psi_r - \sqrt{2} \otimes G)$. Due to their similarity, we take $\delta_1^F$ as example and the same analysis applies to $\delta_2^F$ with obvious modification. For $\delta_1^F$, we further decompose it as
\[
\delta_1^F = L_1[(\psi_r - G) \otimes \beta_N + G \otimes (\beta_N - \sqrt{2})].
\]

By (43), the essential elements we need to bound are $\|D^{(k)}(\psi_r - G)\|_\pm$, $\|D^{(k)}G\|_\pm$ and $\|1\|_-$ for $k = -1$ and $0$. The bounds related to $D^{(k)}(\psi_r - G)$ have already been obtained. For the other two terms, (44) and Lemma\textsuperscript{1} give
\[
\|D^{(k)}G\|_\pm^2 \leq C(s_0) \exp(-2s' + |s'|),
\]
and
\[
\|1\|_-^2 = \int_{s'}^{\infty} [1 + \exp(|s|)]^{-1} ds \leq \int_{-\infty}^{\infty} \exp(-|s|) ds \leq 2.
\]

Since $\beta_N - \sqrt{2} = O(N^{-1})$ [for a proof, see A.1], we have
\[
\|\delta_1^F\|_1 \leq \|\psi_r - G\|_1 + \|G \otimes (\beta_N - 1/\sqrt{2})\|_1 \leq \|\psi_r - G\|_1 + \|\beta_N - 1/\sqrt{2}\|_1 \leq C(s_0)N^{-2/3} \exp(-s' + |s'|/2) + C(s_0)N^{-1} \exp(-s' + |s'|/2) \leq C(s_0)N^{-2/3} \exp(-s'/2).
\]

In a similar vein, the same bound can be obtained for $\|\delta_1^F\|_2$ and entries of $\delta_2^F$. Therefore, we conclude that
\[
\|\delta_1^F\|, \|\delta_2^F\|_2 \leq C(s_0)N^{-2/3} \exp(-s'/2). \quad \text{(46)}
\]

Now we prove Theorem\textsuperscript{1}.

Proof of Theorem\textsuperscript{1} By the decomposition (34) and bounds (42), (45) and (46), the triangle inequality gives the following bound for the norm of each entry in $K_r - K_{GOE}$:
\[
\|(K_r - K_{GOE})_{ij}\| \leq C(s_0)N^{-2/3} \exp(-s'/2).
\]
We then apply Proposition 1 with $A = K_{\tau}$ and $B = K_{\text{GOE}}$ to get
\[
|\det(I - K_{\tau}) - \det(I - K_{\text{GOE}})| \leq M(K_{\text{GOE}})C(s_0)N^{-2/3}\exp(-s'/2),
\]
(47)
where $M(K_{\text{GOE}}) = 2\det(I - K_{\text{GOE}}) + 2\exp\{2(1 + \|K_{\text{GOE}}\|_2^2 + \sum_i \|K_{\text{GOE},ii}\|_1)\}.$

For the first term in $M(K_{\text{GOE}})$, we have $\det(I - K_{\text{GOE}}) = F_1^2(s') \leq 1$. On the other hand, we have
\[
\|K_{\text{GOE}}\|_2 \leq \sum_{i,j} \|(K_{\text{GOE}})_{ij}\|_2 \leq \sum_i \|(K_{\text{GOE}})_{ii}\|_1 + \sum_{i\neq j} \|(K_{\text{GOE}})_{ij}\|_2.
\]

In principle, one can show that, for each $(i,j)$, $\|(K_{\text{GOE}})_{ij}\| \leq C(s_0)$, with $C(s_0)$ continuous and non-increasing. Take $\|(K_{\text{GOE}})_{11}\|_1$ as an example. Let $H_\tau$ and $G_\tau$ be Hilbert-Schmidt operators with kernels $\phi_\tau(x + y)$ and $\psi_\tau(x + y)$ respectively, then as an operator
\[
(K_{\text{GOE}})_{11} = H_\tau G_\tau + G_\tau H_\tau + G \otimes \frac{1}{\sqrt{2}} - G \otimes \tilde{\varepsilon}G.
\]
Since $\|AB\|_1 \leq \|A\|_2\|B\|_2$, we have
\[
\|(K_{\text{GOE}})_{11}\|_1 \leq 2\|H_\tau\|_2\|G_\tau\|_2 + \frac{1}{\sqrt{2}}\|G\|_{2,\rho} \|1\|_{2,\rho^{-1}} + \|G\|_{2,\rho} \|\tilde{\varepsilon}G\|_{2,\rho^{-1}}.
\]
Each norm on the right side of the last inequality is the square root of an integral of a positive function on $(s', \infty)$ or $(s', \infty)^2$ that is bounded by the corresponding integral over $(s_0, \infty)$ or $(s_0, \infty)^2$, which in turn is continuous and non-increasing in $s_0$. Hence, $\|(K_{\text{GOE}})_{11}\|_1 \leq C(s_0).$ Similar argument applies to other entries. So, we can control $M(K_{\text{GOE}})$ by a continuous and non-increasing $C(s_0)$. Finally, we complete the proof by noting (30) and the fact that $1/F_1(s_0)$ is continuous and non-increasing. 

\[\square\]

4 The Smallest Eigenvalue

This section is dedicated to the proof of Theorem 2.

Recall that two key components in the proof of Theorem 1 were: (1) determinantal representations for both the finite and the limiting distributions; (2) a closed form formula for the finite sample kernel which yields a convenient decomposition of its difference from the limiting kernel.

In what follows, we first establish the rate of convergence for matrices with even dimensions. This is achieved by working out the above two components in the case of the smallest eigenvalue. Then, we prove weak convergence for matrices with odd dimensions using an interlacing property of the singular values.

4.1 Determinantal Formula

As before, we follow RMT notation to replace $p$ with $N$, and identify LOE($N, \alpha$) with eigenvalues of $A \sim W_N(I, n)$ by $\tilde{\chi}$.

Assume that $N$ is even. For the smallest eigenvalue $x_N$, for any $x' \geq 0$, [31] gives
\[
1 - \tilde{F}_{N,N}(x') = P\{x_N > x'\} = \sqrt{\det(I - K_{\chi}N)},
\]
(48)
where $\chi = 1_{0 \leq x \leq x'}$ and $K_{\chi}$ is given in (10).

Due to a nonlinear transformation to be introduced, the formula (12) that we previously used to represent $S_{N,1}$, the key component in $K_{\chi}$, is not most appropriate here. Instead, we find an alternative (yet equivalent) formula given in [1] Proposition 4.2 more convenient. Indeed, let
\[
\tilde{\phi}_k(x; \alpha) = (-1)^k \sqrt{\frac{a_N}{2}} \phi_k(x; \alpha)x^{-1/2} 1_{x \geq 0},
\]
(49)
with \( a_N = \sqrt{N(N+\alpha)} \), then \[1\] Proposition 4.2 asserts that

\[
S_{N,1}(x, y; \alpha) = \sqrt{\frac{y}{x}} S_{N-1,2}(x, y; \alpha + 1) + \sqrt{\frac{N-1}{N}} \phi_{N-1}(x; \alpha + 1)(\bar{\epsilon} \phi_{N-2})(y; \alpha + 1). \tag{50}
\]

We write out the explicit dependence of these kernels on the parameter \( \alpha \) as they are different on the two sides of the equation. As a comparison, the previous representation (15) could be rewritten as

\[
S_{N,1}(x, y; \alpha) = S_{N,2}(x, y; \alpha) + \phi_{N-1}(x; \alpha + 1)(\bar{\epsilon} \phi_{N})(y; \alpha - 1).
\]

Its equivalence to (50) is given in \[1\] Appendix.

Now, introduce the nonlinear transformation

\[
\pi(s) = \exp(\nu_{n,N} - s \tau_{n,N}), \tag{51}
\]

where \( \nu_{n,N} \) and \( \tau_{n,N} \) are the rescaling constants in (6), with \( p \) replaced by \( N \). Incorporating the transformation into \( \tilde{K}_s \), we define

\[
\tilde{K}_s(s, t) = \sqrt{\pi'/(s) \pi'(t)} K_N(\pi(s), \pi(t)). \tag{52}
\]

Let \( F_{N,N} \) be the distribution of \((\log x_N - \nu_{n,N})/\tau_{n,N} \). Fix \( s_0 \), for any \( s' = \pi^{-1}(s') \geq s_0 \) and \( f = 1_{s' \geq s'} \), since \( \det(I - K_s f) = \det(I - K_s f) \), we obtain \( 1 - F_{N,N}(-s') = \sqrt{\det(I - K_s f)} \). Thinking of \( K_s \) as a Hilbert-Schmidt operator with trace class diagonal entries on \( L^2([s', \infty); \rho) \oplus L^2([s', \infty); \rho^{-1}) \) for proper weight function \( \rho \), we can drop \( f \).

Now consider the representation of \( \tilde{K}_s \). For \( b_N = \sqrt{(N-1)/N} \), let

\[
\phi_\pi(s) = -\sqrt{b_N \pi'(s)} \phi_{N-2}(\pi(s); \alpha + 1), \quad \psi_\pi(s) = \sqrt{b_N \pi'(s)} \phi_{N-1}(\pi(s); \alpha + 1). \tag{53}
\]

Using \[1\] Proposition 5.4.2, we obtain

\[
S_{N-1,2}(\pi(s), \pi(t); \alpha + 1) = (\pi'(s) \pi'(t))^{-1/2}(\phi_\pi \circ \psi_\pi + \psi_\pi \circ \phi_\pi)(s, t).
\]

On the other hand, simple manipulation yields that the second term in (50), with \( x = \pi(s) \) and \( y = \pi(t) \), equals \((\pi'(s))^{-1} \psi_\pi(s) (\bar{\epsilon} \phi_{N})(s, t) \). Thus, \( S_{N,1}(\pi(s), \pi(t)) = (\pi'(s))^{-1} S^R_{\pi}(s, t) \) with

\[
S^R_{\pi}(s, t) = (\phi_\pi \circ \psi_\pi + \psi_\pi \circ \phi_\pi)(s, t) + (\psi_\pi \circ \bar{\epsilon} \phi_{N})(s, t). \tag{54}
\]

In addition, we have

\[
(-\partial_2 S_{N,1})(\pi(s), \pi(t)) = \frac{-\partial_1 S_{N,1}(\pi(s), \pi(t))}{\partial t \pi(t)} = \frac{-1}{\pi'(s) \pi'(t)} \cdot [-\partial_2 S^R_{\pi}(s, t)],
\]

\[
(\varepsilon_1 S_{N,1})(\pi(s), \pi(t)) = \int_0^\infty \varepsilon(\pi(z) - \pi(s)) S_{N,1}(z, \pi(t)) dz
\]

\[
= \int_{-\infty}^\infty \varepsilon(s - u) S_{N,1}(\pi(u), \pi(t)) \pi'(u) du = -(\varepsilon_1 S^R_{\pi})(s, t).
\]

Supplying these equations to \[10\], we obtain that

\[
\tilde{K}_s(\pi(s), \pi(t)) = U(s)(LS^R_{\pi} + K^s)(s, t) U^{-1}(t)
\]

with \( U(s) = \text{diag}(1/\sqrt{-\pi'(s)}, -\sqrt{-\pi'(s)}) \). Observe that \( \det(I - K_s) \) remains unchanged if we premultiply \( \tilde{K}_s \) with \( U^{-1}(s_0) \) and postmultiply it with \( U(s_0) \). Denote the resulting kernel by \( K_s \), we obtain that

\[
K_{\pi}(s, t) = Q_N(s)(LS^R_{\pi} + K^s)(s, t) Q_N^{-1}(t) \tag{55}
\]
with \( Q_N(s) = U^{-1}(s_0)U(s) = \text{diag}(\sqrt{\pi'(s_0)/\pi'(s)}, \sqrt{\pi'(s)/\pi'(s_0)}) \), and that \( 1 - F_{N,N}(-s') = \sqrt{\det(I - K_{\pi})} \).

Recall that \( G_1(-s') = 1 - F_1(s') \). So, \( F_{N,N}(-s') - G_1(-s') = F_1(-s') - [1 - F_{N,N}(-s')] \).

Similar to (50), we obtain
\[
|F_{N,N}(-s') - G_1(-s')| \leq \frac{1}{F_1(s_0)}|\det(I - K_{\pi}) - \det(I - K_{GOE})|.
\]

Thus, as in the case of the largest eigenvalue, by Proposition 1 to prove Theorem 2 is to control the entrywise norm of \( K_{\pi} - K_{GOE} \). For this purpose, a convenient decomposition of \( K_{\pi} - K_{GOE} \) is crucial, to which we now turn.

### 4.2 Kernel Difference Decomposition

We derive below a decomposition of \( K_{\pi} - K_{GOE} \). Despite the differences in actual formulas, the general guideline of the decomposition is the same as that in Section 3.4.

To start with, we rewrite (55) using the right tail integration operator \( \tilde{\varepsilon} \). To this end, observe that \( \int \psi_{\pi} = 0 \) and that
\[
\tilde{\beta}_N = \frac{1}{2} \int_{-\infty}^{\infty} \phi_{\pi}(s)ds = \frac{(N - 1)^{1/4}(n - 1)^{1/4} \Gamma \left( \frac{N+1}{2} \right)}{2^{(n-N)/2}(N-1)} \left[ \frac{\Gamma(n-1)}{\Gamma(N-1)} \right]^{1/2} = \frac{1}{\sqrt{2}} + O(N^{-1}).
\]

By the same argument that leads to (27), we obtain
\[
K_{\pi}(s,t) = Q_N(s)(K^R_{\pi} + K^F_{\pi,1} + K^F_{\pi,2} + K^\varepsilon)(s,t)Q_N^{-1}(t),
\]
with the unspecified components given by
\[
K^R_{\pi} = \tilde{L}(S_{\pi} - \psi_{\pi} \otimes \tilde{\varepsilon} \phi_{\pi}), \quad K^F_{\pi,1} = L_1(\psi_{\pi} \otimes \tilde{\beta}_N), \quad K^F_{\pi,2} = L_2(\tilde{\beta}_N \otimes \psi_{\pi}).
\]

Define \( \tilde{\Delta}_N = (\nu_{n,N} - \nu_{n-1,N-1})/\tau_{n-1,N-1} = O(N^{-1/3}) \) and \( \tilde{G}_N = G + \tilde{\Delta}_N G' \). For \( \tilde{S}_{AN} = G \circ \tilde{G}_N + \tilde{G}_N \circ G \), we have \( \tilde{S}_{AN} - G \otimes \tilde{G}_N = S_A - G \otimes G \). Abbreviate the terms in (18) as
\[
K_{GOE} = K^R + K^F_1 + K^F_2 + K^\varepsilon.
\]

Then,
\[
K^R_{\pi} - K^R = \tilde{L}(S_{\pi} - S_A - \psi_{\pi} \otimes \tilde{\varepsilon} \phi_{\pi} + G \otimes \tilde{\varepsilon} G) = \tilde{L}(S_{\pi} - \tilde{S}_{AN}) - \tilde{L}(\psi_{\pi} \otimes \tilde{\varepsilon} \phi_{\pi} - G \otimes \tilde{\varepsilon} G_N) = \delta_{R,I} + \delta_{0,F}.
\]

Further define
\[
\delta^{R,D}(s,t) = Q_N(s)K^R_{\pi}(s,t)Q_N^{-1}(t) - K^R_{\pi}(s,t),
\]
\[
\delta^i_F(s,t) = Q_N(s)K^F_{\pi,i}(s,t)Q_N^{-1}(t) - K^F_{\pi,i}(s,t), \quad i = 1,2,
\]
\[
\delta^\varepsilon(s,t) = Q_N(s)K^\varepsilon(s,t)Q_N^{-1}(t) - K^\varepsilon(s,t).
\]

Our final decomposition of \( K_{\pi} - K_{GOE} \) is
\[
K_{\pi} - K_{GOE} = \delta^{R,D} + \delta_{R,I} + \delta^F_0 + \delta^F_1 + \delta^F_2 + \delta^\varepsilon. \tag{56}
\]

We remark that Proposition 2 remains valid if we replace \( \phi_\pi \) and \( \psi_\pi \) with \( \phi_{\pi} \) and \( \psi_{\pi} \) respectively. The proof is similar to that to be presented in Section 3.5 for Proposition 2. With these estimates, for each term in (56), we apply Lemma 2 to bound their entrywise norms as in Section 3.6. This completes the proof of the rate of convergence part in Theorem 2.
4.3 Weak Convergence in the Odd \( N \) Case

We now establish weak convergence to the reflected Tracy-Widom law in the odd \( N \) case. This is achieved by employing an interlacing property of the singular values. The strategy follows from [30, Remark 5].

Assume that \( N \) is odd and \( n - 1 \geq N \). Let \( X_{N+1} \) be an \((n+1)\times(N+1)\) matrix with i.i.d. \( N(0,1) \) entries and \( X_N \) the \( n \times N \) matrix obtained by deleting the last row and the last column of \( X_{N+1} \). Denote the smallest singular values of \( X_{N+1} \) and \( X_N \) by \( \iota_{N+1} \) and \( \iota_N \) respectively. We apply [13, Theorem 7.3.9] twice to obtain that \( \iota_N \leq \iota_{N+1} \). Repeat the deletion operation on \( X_N \) to obtain the \((n-1)\times(N-1)\) matrix \( X_{N-1} \) and denote its smallest singular value by \( \iota_{N-1} \). Then we obtain the “sandwich” relation: \( \iota_{N-1} \leq \iota_N \leq \iota_{N+1} \).

Observe that for \( k = N - 1, N \) and \( N + 1 \), \( X_k'X_k \) are white Wishart matrices with the smallest eigenvalues \( s_k = \iota_k^2 \). In addition, as \( N \to \infty \) and \( n/N \to \gamma > 1 \),

\[
\left( \nu_{n,N}^- - \nu_{n-1,N-1}^- \right)/\tau_{n-1,N-1}^- = O(N^{-1/3}) \quad \text{and} \quad \tau_{n,N}/\tau_{n-1,N-1}^- = 1 + O(N^{-1}).
\]

They together imply that the weak limits for the odd \( N \) and the even \( N \) sequences must be the same. This completes the proof of Theorem 2.

5 Laguerre Polynomial Asymptotics

In this section, we complete the proof of Proposition 2. The proof has the following components: first, we take the Liouville-Green approach to analyze an intermediate function that is connected to both \( \phi_\tau \) and \( \psi_\tau \). After recollecting some previous results in [10, 15] for \( \psi_\tau \), we give a detailed analysis of \( \psi', \psi' - G' \) and also strengthen a previous bound on \( \psi - G \). Finally, we transfer the bounds on quantities related to \( \psi_\tau \) to those related to \( \phi_\tau \) by a change of variable argument.

5.1 Liouville-Green Approach

Recall \((\tilde{\mu}_{n,N}, \tilde{\sigma}_{n,N})\) in (32) and \( \alpha \) in (5). We introduce the intermediate function

\[
F_{n,N}(x) = (-1)^N \tilde{\sigma}_{n,N}^{-1/2} \sqrt{N!/n!} x^{\alpha/2 + 1} e^{-x/2} L_N^{\alpha+1}(x)
\]

as in [15, Eq. (5.1)] and [10, Section 2.2.2]. Then \( \phi_\tau \) is related to \( F_{n,N} \) as

\[
\psi_\tau(s) = \frac{1}{\sqrt{2}} \left( \frac{N^{1/4}(n-1)^{1/4}\tilde{\sigma}_{n-1,N-1}\sigma_{n,N}}{\tilde{\mu}_{n-1,N-1}} \right) F_{n-1,N-1}(\mu_{n,N} + s\sigma_{n,N}) \left( \frac{\tilde{\mu}_{n-1,N-1}}{\tilde{\mu}_{n,N} + s\sigma_{n,N}} \right).
\]

Replacing the subscripts \((n-1,N-1)\) by \((n-2,N)\) in \( \tilde{\mu}_{n-1,N-1}, \tilde{\sigma}_{n-1,N-1} \) and \( F_{n-1,N-1} \) on the right side, we also obtain the expression for \( \phi_\tau(s) \).

Due to the close connection of \( \psi_\tau \) and \( \phi_\tau \) to \( F_{n,N} \), the key element in the proof of Proposition 2 becomes asymptotic analysis of \( F_{n,N} \) and its derivative. To this end, the Liouville-Green (LG) theory set out in Olver [26, Chapter 11] is useful, for it comes with ready-made bounds on the difference between \( F_{n,N} \) and the Airy function, and also on the difference between their derivatives.

To start with, we observe that \( F_{n,N} \) satisfies a second order differential equation

\[
F''_{n,N}(x) = \left\{ \frac{1}{4} - \frac{\kappa_N}{x} + \frac{\lambda_N^2 - 1/4}{x^2} \right\} F_{n,N}(x),
\]

\[\text{Note: } \alpha = \alpha_N - 1 \text{ for the constant } \alpha_N \text{ used in [15] and [10].}\]
with \( \kappa_N = \frac{1}{2}(n + N + 1) \) and \( \lambda_N = \frac{1}{2}(n - N) \). By a rescaling \( x = \kappa_N \xi \), setting \( w_N(\xi) = F_{n,N}(x) \), the equation becomes

\[
\ddot{w}_N^\prime(\xi) = \{\kappa_N^2 f(\xi) + g(\xi)\} w_N(\xi),
\]

where

\[
f(\xi) = \frac{\xi - \xi_-(\xi - \xi_+)}{4\xi^2}, \quad g(\xi) = \frac{1}{4\xi^2}.
\]

The zeros of \( f \) are given by \( \xi_\pm = 2 \pm \sqrt{4 - \omega_N^2} \) for \( \omega_N = 2\lambda_N/\kappa_N \). They are called the turning points of the differential equation, for each separates an interval in which the solutions are oscillating from one in which they are of exponential type. The LG approach introduces new independent variable \( \zeta \) and dependent variable \( W \) as

\[
\zeta \left( \frac{d\zeta}{d\xi} \right)^2 = f(\xi), \quad W = \left( \frac{d\zeta}{d\xi} \right)^{1/2} w_N.
\]

Then the differential equation takes the form \( W''(\zeta) = \{\kappa_N^2 \zeta + v(\omega_N, \zeta)\} W(\zeta) \). Without the perturbation term \( v(\omega_N, \zeta) \), this is the Airy equation having linearly independent solutions in terms of Airy functions \( \text{Ai}(\kappa_N^{2/3} \zeta) \) and \( \text{Bi}(\kappa_N^{2/3} \zeta) \). We focus on approximating the recessive solution \( \text{Ai}(\kappa_N^{2/3} \zeta) \).

Let \( \tilde{f} = f/\zeta \). [26, Theorem 11.3.1] gives that

\[
w_N(\xi) \sim \tilde{f}^{-1/4}(\xi)\{\text{Ai}(\kappa_N^{2/3} \zeta) + \varepsilon_2(\kappa_N, \xi)\},
\]

where uniformly for \( \xi \in [2, \infty) \), the error term \( \varepsilon_2 \) satisfies

\[
|\varepsilon_2(\kappa_N, \xi)| \leq (\mathcal{M}/\mathcal{E})(\kappa_N^{2/3} \zeta) [\exp\{\lambda_0 F(\omega_N)/\kappa_N\} - 1], \quad (59)
\]

\[
|\partial_\xi \varepsilon_2(\kappa_N, \xi)| \leq \kappa_N^{2/3} \tilde{f}^{1/2}(\xi)(\mathcal{N}/\mathcal{E})(\kappa_N^{2/3} \zeta) [\exp\{\lambda_0 F(\omega_N)/\kappa_N\} - 1]. \quad (60)
\]

In the bounds, \( \mathcal{M}, \mathcal{E} \) are the modulus and weight functions for the Airy function, and \( \mathcal{N} \) the phase function for its derivative [26 pp.394-396]. On the real line, \( \mathcal{E} \geq 1 \) and is increasing, \( 0 \leq \mathcal{M} \leq 1 \) and \( \mathcal{N} \geq 0 \). Moreover, for all \( x \),

\[
|\text{Ai}(x)| \leq (\mathcal{M}/\mathcal{E})(x), \quad |\text{Ai}'(x)| \leq (\mathcal{N}/\mathcal{E})(x). \quad (61)
\]

As \( x \to \infty \), their asymptotics are given by

\[
\mathcal{E}(x) \sim \sqrt{2} e^{\frac{3}{4} x^{3/2}}, \quad \mathcal{M}(x) \sim \pi^{-1/2} x^{-1/4}, \quad \mathcal{N}(x) \sim \pi^{-1/2} x^{1/4}. \quad (62)
\]

In addition, in the bounds [59] and [60], \( \lambda_0 \approx 1.04 \) and the analysis in [10, A.3] shows that, uniformly for \( \xi \in [2, \infty) \), for large enough \( \mathcal{N} \),

\[
\exp\{\lambda_0 F(\omega_N)/\kappa_N\} - 1 \leq \mathcal{N}^{-2/3}. \quad (63)
\]

Come back to \( F_{n,N} \). The alignment in [10] Eq.(5) and A.1] shows that

\[
F_{n,N}(x) = r_N^{1/6} \sigma_{n,N}^{1/2} \tilde{f}^{-1/4}(\xi)\{\text{Ai}(\kappa_N^{2/3} \zeta) + \varepsilon_2(\kappa_N, \xi)\},
\]

21
with \( r_N = 1 + O(N^{-1}) \). Let \( R_N(\xi) = (\zeta'(\xi)/\zeta_N')^{-1/2} \) with \( \zeta_N' = \zeta'(\xi_+) \). As \( (\zeta_N')^{-1} = \kappa_N^{1/3} \tilde{\sigma}_{n,N} \) and \( f(\xi) = \zeta'(\xi)^2 \), we can rewrite \( F_{n,N} \) as

\[
F_{n,N}(x) = r_N R_N(\xi) \{ \text{Ai}(\kappa_N^{2/3} \zeta) + \varepsilon_2(\kappa_N, \xi) \}. \tag{64}
\]

This representation serves as the starting point for all the subsequent asymptotic analysis on \( \phi_\tau \), \( \psi_\tau \) and their derivatives.

From now on, without notice, all the inequalities are understood to hold uniformly for \( N \geq N_0(s_0, \gamma) \).

### 5.2 Summary of Previous Analysis: Bound for \( |\psi_\tau(s)| \)

Here, we summarize some previous analysis of \( F_{n,N} \) in \cite{15, 10}, which gives the desired bound for \( |\psi_\tau(s)| \) in \cite{35}, and a crude estimate for \( |\psi_\tau - G| \).

Let \( x_{n,N}(s) = \tilde{\mu}_{n,N} + s \tilde{\sigma}_{n,N} \) and define

\[
\theta_{n,N}(x_{n,N}(s)) = F_{n,N}(x_{n,N}(s)) \left( \frac{\tilde{\mu}_{n,N}}{x_{n,N}(s)} \right), \tag{65}
\]

As \( \tilde{\sigma}_{n,N}^{-1/2} N^{1/6} < 1 \), we obtain that, for all \( s \geq 0 \),

\[
|F_{n,N}(x_{n,N}(s))| \leq |F_{n,N}(x_{n,N}(s))\tilde{\sigma}_{n,N}^{-1/2} N^{-1/6}| \leq C \exp(-s),
\]

where the later inequality was obtained in \cite[A.8]{15}. If \( s_0 < 0 \), then \( \xi = x_{n,N}(s)/\kappa_N \geq 2 \) uniformly for all \( s \geq s_0 \). In addition, Lemma 3 later shows that \( |R_N(\xi)| \leq 1 + CN^{-2/3}|s| \) for \( s \in [s_0, 0] \).

Therefore, we apply \cite{59, 63} and \cite{64} to obtain that

\[
|F_{n,N}(x_{n,N}(s))| \leq 2r_N |R_N(\xi)| (\mathcal{M}/\mathcal{E})(\kappa_N^{2/3} \zeta) \leq 4,
\]

uniformly for \( s \in [s_0, 0] \). Hence, \( |F_{n,N}(x_{n,N}(s))| \leq C \exp(-s) \) for all \( s \geq s_0 \). Moreover, we note that \( \tilde{\sigma}_{n,N}/\tilde{\mu}_{n,N} = O(N^{-2/3}) \). So, when \( N \geq N_0(s_0) \), for all \( s \geq s_0 \),

\[
\tilde{\mu}_{n,N}/x_{n,N}(s) \leq (1 + s_0 \tilde{\sigma}_{n,N}/\tilde{\mu}_{n,N})^{-1} \leq 2.
\]

Hence, uniformly for \( s \geq s_0 \),

\[
|\theta_{n,N}(x_{n,N}(s))| \leq C(s_0) \exp(-s). \tag{66}
\]

Finally, for any \( \varrho_N = 1 + O(N^{-1}) \), El Karoui \cite[Section 3.2]{10} showed that, for all \( s \geq s_0 \),

\[
|\varrho_N \theta_{n,N}(x_{n,N}(s)) - \text{Ai}(s)| \leq C(s_0) N^{-2/3} \exp(-s/2).
\]

For \( \psi_\tau(s) \), observe that \( (\mu_{n,N}, \sigma_{n,N}) = (\tilde{\mu}_{n-1,N-1}, \tilde{\sigma}_{n-1,N-1}) \). Using Sterling’s formula, we obtain that \( \psi_\tau(s) = \frac{1}{2\sqrt{\rho_N}} \rho_N \theta_{n-1,N-1}(x_{n-1,N-1}(s)) \) for some \( \rho_N = 1 + O(N^{-1}) \). Then, we apply the last two displays to obtain

\[
|\psi_\tau(s)| \leq C(s_0) \exp(-s), \quad |\psi_\tau(s) - G(s)| \leq C(s_0) N^{-2/3} \exp(-s/2), \tag{67}
\]

uniformly for \( s \geq s_0 \).

Here, the first inequality gives the bound for \( |\psi_\tau| \), while the bound on \( |\psi_\tau(s) - G(s)| \) could be further improved: see \cite{73}. Note that we can not apply these results directly to \( \phi_\tau \) since the ‘optimal’ rescaling constants \( (\tilde{\mu}_{n-2,N}, \tilde{\sigma}_{n-2,N}) \) for \( F_{n-2,N} \) does not agree with the global constants \( (\mu_{n,N}, \sigma_{n,N}) \).
5.3 Asymptotics of $|\psi'_r(s)|$, $|\psi'_r(s) - G'(s)|$ and $|\psi_r(s) - G(s)|$

Here, we derive bounds on $|\psi'_r|$ and $|\psi'_r - G'|$, and refine the bound on $|\psi_r(s) - G(s)|$.

5.3.1 Bound for $|\psi'_r(s)|$

To obtain bound for $|\psi'_r|$, we study $|\partial_s \theta_{n,N}(x_{n,N}(s))|$. By the triangle inequality,

$$
|\partial_s \theta_{n,N}(x_{n,N}(s))| \leq |\tilde{\sigma}_{n,N} F'_{n,N}(x_{n,N}(s)) \frac{\tilde{\mu}_{n,N}}{x_{n,N}(s)}| + |\tilde{\sigma}_{n,N} F_{n,N}(x_{n,N}(s)) \frac{\tilde{\mu}_{n,N}}{x_{n,N}(s)}|
$$

(68)

$$
= T_{N,1}(s) + T_{N,2}(s).
$$

In what follows, we deal with the two terms in order.

**The $T_{N,1}$ term.** Recall that $\tilde{\mu}_{n,N}/x_{n,N}(s) \leq 2$ for large $N$. So, we focus on $\tilde{\sigma}_{n,N} F'_{n,N}$, which can be decomposed as $\tilde{\sigma}_{n,N} F'_{n,N} = \sum_{i=1}^{4} D_{n,N}^i$, with

$$
D_{n,N}^1 = r_N \tilde{\sigma}_{n,N} \tilde{R}'_N(\xi) \{ \text{Ai}(\kappa_N^{2/3} \xi) + \varepsilon_2(\kappa_N, \xi) \},
$$

$$
D_{n,N}^2 = r_N \{ \text{Ai}(\kappa_N^{2/3} \xi) \},
$$

$$
D_{n,N}^3 = r_N \tilde{\sigma}_{n,N} \kappa_N^{-1} R_N(\xi),
$$

$$
D_{n,N}^4 = r_N \tilde{\sigma}_{n,N} \kappa_N^{-1} R_N(\xi) \partial_\xi \varepsilon_2(\kappa_N, \xi).
$$

Due to different strategies used for the asymptotics, on the $s$-scale, we divide $[s_0, \infty)$ into $I_{1,N} \cup I_{2,N}$, with $I_{1,N} = [s_0, s_1 N^{1/6}]$ and $I_{2,N} = [s_1 N^{1/6}, \infty)$. The choice of $s_1$ is worked out in A.2. For here, we note that $s_1 \geq 1$ and that for $s \geq s_1$,

$$
E^{-1}(\kappa_N^{2/3} \xi) \leq C \exp(-3s/2) \leq C \exp(-s).
$$

(69)

In addition, we will repeatedly use the following facts.

**Lemma 3.** Under the condition of Proposition 3, when $N \geq N_0(s_0, \gamma)$, for all $s \in I_{1,N}$,

$$
|R_N(\xi)| \leq C \gamma^{-1/2} (1 + \gamma), \quad |R_N(\xi) - 1| \leq C N^{-2/3} s, \quad |\kappa_N^{2/3} \xi - s| \leq (CN^{-2/3} s^2) \wedge \frac{1}{2} |s| \wedge 1.
$$

Proof of Lemma 3 is given in [22].

**Case $s \in I_{1,N}$.** Consider $D_{n,N}^1$ first. Recall that $r_N = 1 + O(N^{-1})$. Together with Lemma 3 this implies

$$
|r_N \tilde{\sigma}_{n,N} \kappa_N^{-1} R_N(\xi)| \leq C N^{-2/3}.
$$

(70)

On the other hand, as $0 \leq M \leq 1$, [59], (61) and (63) together imply

$$
|\text{Ai}(\kappa_N^{2/3} \xi) + \varepsilon_2(\kappa_N, \xi)| \leq C (M/E)(\kappa_N^{2/3} \xi) \leq C E^{-1}(\kappa_N^{2/3} \xi).
$$

For $s \geq 0$, Lemma 3 implies $\kappa_N^{2/3} \xi \geq s/2$. Since $E$ is monotone increasing, by (62),

$$
|\text{Ai}(\kappa_N^{2/3} \xi) + \varepsilon_2(\kappa_N, \xi)| \leq C E^{-1}(s/2) \leq C e^{-\frac{1}{3} s^{3/2}} \leq C \exp(-s).
$$

If $s_0 \leq 0$, we can replace the $C$ on the rightmost side with $C(s_0) = \max\{C, \max_{s \in [s_0, 2]} E^{-1}(s)\}$, which is continuous and non-increasing in $s_0$. Together with (70), we obtain that

$$
|D_{n,N}^1| \leq C(s_0) N^{-2/3} \exp(-s).
$$

4Here and after, we derive more stringent bounds with the $N^{-2/3}$ term whenever possible. Although they are not necessary for bounding $|\psi'_r|$, they are useful in the later study of $|\psi_r(s) - G(s)|$. 

23
For $D_{n,N}^2$, we first have $|r_N R_N^{-1}(\xi) - 1| \leq r_N |R_N^{-1}(\xi) - 1| + |r_N - 1|$. Lemma 3 implies that $|R_N^{-1}(\xi) - 1| \leq C N^{-2/3} |s|$. Observing that $|r_N - 1| = O(N^{-1})$, we obtain

$$|r_N R_N^{-1}(\xi) - 1| \leq C N^{-2/3} |s|.$$  

For $|A_i'(\kappa_N^{2/3} \zeta)|$, when $s \geq 0$, Lemma 3 gives $\kappa_N^{2/3} \zeta \in [s/2, 3s/2]$. This, together with Lemma 1, implies that

$$|A_i'(\kappa_N^{2/3} \zeta)| \leq C \exp(-3s/2). \quad (71)$$

If $s_0 < 0$, we can replace the $C$ on the right side with $C(s_0) = \max\{C, \max_{s_0 \in [3s_0/2, 0]} |A_i'(s)|\}$, which is continuous and non-increasing. Then, the last two displays give

$$|D_{n,N}^2| \leq C(s_0) N^{-2/3} |s| \exp(-3s/2) \leq C(s_0) N^{-2/3} \exp(-s).$$

For $D_{n,N}^3$, we recall that $r_N = 1 + O(N^{-1})$. Together with (71), this implies that

$$|D_{n,N}^3| \leq C(s_0) \exp(-s).$$

For $D_{n,N}^4$, since $r_N = 1 + O(N^{-1})$, $\zeta' = \sqrt{\sqrt{2}} \xi$ and $\zeta'' = \kappa_N^{1/3} \tilde{\sigma}_{n,N}$, (60) and (63) imply

$$|D_{n,N}^4| = \left| r_N \tilde{\sigma}_{n,N} \kappa_N^{-1} R_N(\xi) \partial_{\xi} \tilde{\epsilon}_2(\kappa_N, \xi) \right| \leq C N^{-2/3} \tilde{\sigma}_{n,N} \kappa_N^{-1/3} R_N(\xi) (N/\xi) (\kappa_N^{2/3} \zeta) = C N^{-2/3} R_N^{-1}(\xi) (N/\xi) (\kappa_N^{2/3} \zeta).$$

Lemma 3 implies that $R_N^{-1}(\xi) \leq C$ and $\kappa_N^{2/3} \zeta \in [s/2, 3s/2]$, uniformly on $I_{1,N}$. So, (62) gives

$$(N/\xi) (\kappa_N^{2/3} \zeta) \leq C s^{-1/4} e^{-1/3 \sqrt{s}} \leq C \exp(-s),$$

for all $s \geq 0$. And if $s_0 < 0$, we can replace the $C$ on the rightmost side with $C(s_0) = \max\{C, \max_{s_0 \in [3s_0/2, 0]} (N/\xi)(s)\}$, which is continuous and non-increasing in $s_0$. All these elements together lead to

$$|D_{n,N}^4| \leq C(s_0) N^{-2/3} \exp(-s).$$

Combining all the bounds on the $D_{n,N}^i$ terms, we obtain that $T_{N,1} \leq C(s_0) \exp(-s)$ on $I_{1,N}$.

**Case** $s \in I_{2,N}$. In this case, we define $\tilde{D}_{n,N}^1 = D_{n,N}^1$ and $\tilde{D}_{n,N}^2 = D_{n,N}^2 + D_{n,N}^3 + D_{n,N}^4$.

Consider $\tilde{D}_{n,N}^1$ first. By (59), (61) and (63), we obtain that for $N \geq N_0(s_0, \gamma)$,

$$|\tilde{D}_{n,N}^1| \leq C \tilde{\sigma}_{n,N} \kappa_N^{-1} |R_N'| R_N |(\xi) R_N(\xi) (\mathcal{M}/\mathcal{E})(\kappa_N^{2/3} \zeta).$$

Observe that, uniformly on $I_{2,N}$,

$$\tilde{\sigma}_{n,N} \kappa_N^{-1} |R_N'| R_N |(\xi) \leq C, \quad R_N(\xi) \mathcal{M}(\kappa_N^{2/3} \zeta) \leq C s. \quad (72)$$

For a proof of (72), see [22]. On the other hand, (69) holds on $I_{2,N}$. Thus,

$$|\tilde{D}_{n,N}^1| \leq C s \exp(-3s/2) \leq C s^4 \exp(-s) \leq C N^{-2/3} \exp(-s).$$
For $\tilde{D}_{n,N}^2$, we can write it as $\tilde{D}_{n,N}^2 = r_N R_N(\xi)[\operatorname{Ai}'(\kappa_N^{2/3} \xi) R_N^{-2}(\xi) + \tilde{\sigma}_{n,N} \kappa_N^{-1} \partial_\xi \varepsilon_2(\kappa_N, \xi)]$. By (60), (61), (63) and the identity $R_N^{-1} = \tilde{\sigma}_{n,N}^{-1/2} \kappa_N^{1/6} f^{1/4}$, we get the bound

$$|\tilde{D}_{n,N}^2| \leq C R_N^{-1}(\xi)(N/E)(\kappa_N^{2/3} \xi).$$

(62) suggests that $R_N^{-1}(\xi) N(\kappa_N^{2/3} \xi) \leq C R_N^{-1}(\xi)^{1/6} s^{-1/4} = C f^{1/4}(\xi) \tilde{\sigma}_{n,N}^{1/2} \leq C \tilde{\sigma}_{n,N}^{1/2}$. The last inequality holds as $f \leq 4$ for $s \in I_{2,N}$. On the other hand, $\tilde{\sigma}_{n,N} \leq C(\gamma) N^{1/3} \leq C s^4$ for large $N$. Assembling all the pieces, we obtain $R_N^{-1}(\xi) N(\kappa_N^{2/3} \xi) \leq C s^2$. Together with (69), this implies

$$|\tilde{D}_{n,N}^2| \leq C s^2 \exp(-3s/2) \leq C s^{-4} \exp(-s) \leq C N^{-2/3} \exp(-s).$$

Therefore, $T_{N,1} \leq C N^{-2/3} \exp(-s)$ on $I_{2,N}$.

**The $T_{N,2}$ term.** This term is relatively easy to bound. Note that $\tilde{\sigma}_{n,N}/\tilde{\mu}_{n,N} = O(N^{-2/3})$ and that $T_{N,2}(s) = |\theta_{n,N}(x_{n,N}(s)) \tilde{\sigma}_{n,N}/x_{n,N}(s)|$. So, for all $s \geq s_0$, $N \geq N_0(s_0)$,

$$|\tilde{\sigma}_{n,N}/x_{n,N}(s)| = |s + \tilde{\mu}_{n,N}/\tilde{\sigma}_{n,N}|^{-1} \leq C(s_0) N^{-2/3}.$$

Together with (66), this implies that for all $s \geq s_0$, $T_{N,2}(s) \leq C(s_0) N^{-2/3} \exp(-s)$.

**Summing up.** By (68), the bounds on $T_{N,1}$ and $T_{N,2}$ transfer to

$$|\partial_x \theta_{n,N}(x_{n,N}(s))| \leq C(s_0) \exp(-s), \quad (73)$$

uniformly for $s \geq s_0$. On the other hand, we note that

$$\psi'_t(s) = \frac{1}{\sqrt{2}} \rho_N \partial_{s} \theta_{n-1,N-1}(x_{n-1,N-1}(s)),$$

with $\rho_N = 1 + O(N^{-1})$. Thus, (73) implies the desired bound on $|\psi'_t|$ in (65).

### 5.3.2 Bound for $|\psi'_t(s) - G'(s)|$

By the triangle inequality, we bound $|\psi'_t(s) - G'(s)|$ as

$$|\psi'_t(s) - G'(s)| \leq \frac{1}{\sqrt{2}} |\rho_N - 1| |\partial_x \theta_{n-1,N-1}(x_{n-1,N-1}(s))| + \frac{1}{\sqrt{2}} |\partial_x \theta_{n-1,N-1}(x_{n-1,N-1}(s)) - \operatorname{Ai}'(s)|. \quad (74)$$

As $\rho_N = 1 + O(N^{-1})$, by (73), we bound the first term by $C(s_0) N^{-1} \exp(-s)$. In what follows, to bound the second term in (74), we focus on $|\partial_x \theta_{n,N}(x_{n,N}(s)) - \operatorname{Ai}'(s)|$, which can first be split into two parts as:

$$|\partial_x \theta_{n,N}(x_{n,N}(s)) - \operatorname{Ai}'(s)|$$

$$\leq \left| \tilde{\sigma}_{n,N} F_{n,N}(x_{n,N}(s)) - \frac{\tilde{\mu}_{n,N}}{x_{n,N}(s)} - \operatorname{Ai}'(s) \right| + \left| \tilde{\sigma}_{n,N} F_{n,N}(x_{n,N}(s)) - \frac{\tilde{\mu}_{n,N}}{x_{n,N}(s)} \right|$$

$$= T_{N,1}(s) + T_{N,2}(s).$$

**The $T_{N,1}(s)$ term.** For this term, we separate the arguments on $I_{1,N} = [s_0, s_1 N^{1/6})$ and $I_{2,N} = [s_1 N^{1/6}, \infty)$.
Case $s \in I_{1,N}$. On $I_{1,N}$, we decompose $T_{N,1}(s)$ as $T_{N,1}(s) = \sum_{i=1}^{5} D_{n,N}^{i}$, with $D_{n,N}^{i} = D_{n,N}^{i} \mu_{n,N}/x_{n,N}(s)$ for $i = 1, 2$ and 4, and

$$D_{n,N}^{3} = r_{N} \frac{\mu_{n,N}}{x_{n,N}(s)} [A_{i}^{\prime}(\kappa_{N}^{2/3} \zeta) - A_{i}(s)], \quad D_{n,N}^{5} = \left[ r_{N} \frac{\mu_{n,N}}{x_{n,N}(s)} - 1 \right] A_{i}^{\prime}(s).$$

Observe that $|\mu_{n,N}/x_{n,N}(s)| \leq 2$ on $I_{1,N}$. Thus, by previous bounds on $D_{n,N}^{i}$, we obtain that, for $i = 1, 2$ and 4, $|D_{n,N}^{i}| \leq C(s_{0})N^{-2/3} \exp(-s)$.

Consider $D_{n,N}^{3}$. By the Taylor expansion, for some $s^{*}$ between $\kappa_{N}^{2/3} \zeta$ and $s$,

$$|A_{i}^{\prime}(\kappa_{N}^{2/3} \zeta) - A_{i}^{\prime}(s)| \leq |A_{i}^{\prime}(s^{*})| |\kappa_{N}^{2/3} \zeta - s| = |s^{*} A_{i}(s^{*})| |\kappa_{N}^{2/3} \zeta - s|,$$

where the equality comes from the identity $A_{i}^{\prime\prime}(s) = s A_{i}(s)$. By Lemma 3, we have that $|\kappa_{N}^{2/3} \zeta - s| \leq C N^{-2/3} s^{2}$, and that $s^{*}$ lies between $\frac{1}{2}s$ and $\frac{3}{2}s$. The later, together with Lemma 1, implies that, for $s \geq 0$,

$$|s^{*} A_{i}(s^{*})| \leq C \exp(-3s/2).$$

If $s_{0} \leq 0$, we then have $s^{*} \in [\frac{3}{2}s, 0]$, and hence we can replace $C$ on the right side with $C(s_{0}) = \max\{C, \max s_{0} \in [\frac{3}{2}s, 0] |s A_{i}(s)|\}$. Observe that $r_{N} = 1 + O(N^{-1})$ and that $|\mu_{n,N}/x_{n,N}(s)| \leq 2$. We thus conclude that

$$|D_{n,N}^{3}| \leq C(s_{0}) N^{-2/3} s^{2} \exp(-3s/2) \leq C(s_{0}) N^{-2/3} \exp(-s).$$

Switch to $D_{n,N}^{5}$. We first note that

$$\left| r_{N} \frac{\mu_{n,N}}{x_{n,N}(s)} - 1 \right| \leq r_{N} \left| \frac{\mu_{n,N}}{x_{n,N}(s)} - 1 \right| + |r_{N} - 1| = r_{N} |s + \frac{\mu_{n,N}}{\sigma_{n,N}}|^{-1} + |r_{N} - 1| \leq C N^{-2/3} |s| + C N^{-1}. $$

The last inequality holds as $\sigma_{n,N}/\mu_{n,N} = O(N^{-2/3})$, $r_{N} = 1 + O(N^{-1})$, and for large $N$, $|s + \mu_{n,N}/\sigma_{n,N}| \geq \frac{1}{2} \mu_{n,N}/\sigma_{n,N}$ uniformly for $s \in I_{1,N}$. On the other hand, Lemma 1 implies that $|A_{i}^{\prime}(s)| \leq C(s_{0}) \exp(-3s/2)$. Putting the two parts together, we obtain

$$|D_{n,N}^{5}| \leq C(s_{0}) N^{-2/3} (|s| + C N^{-1/3}) \exp(-3s/2) \leq C(s_{0}) N^{-2/3} \exp(-s).$$

Assembling all the bounds on the $D_{n,N}^{i}$‘s, we obtain that, on $I_{1,N}$,

$$T_{N,1}(s) \leq C(s_{0}) N^{-2/3} \exp(-s).$$

Case $s \in I_{2,N}$. In this case, we could act more heavy-handedly. In particular, by the asymptotics of $T_{N,1}(s)$ on $I_{2,N}$ and Lemma 7, we have

$$T_{N,1}(s) \leq \left| \sigma_{n,N} F_{n,N}(x_{n,N}(s)) \right| \frac{\mu_{n,N}}{x_{n,N}(s)} + |A_{i}^{\prime}(s)| \leq C N^{-2/3} \exp(-s) + C \exp(-3s/2) \leq C N^{-2/3} \exp(-s) + C N^{-2/3} s^{4} \exp(-3s/2) \leq C N^{-2/3} \exp(-s).$$

The $T_{N,2}(s)$ term. The $T_{N,2}(s)$ term is the same as $T_{N,2}(s)$ defined previously in the study of $\partial_{\theta} \theta_{n,N}(x_{n,N}(s))$ and hence we quote the bound derived there directly as

$$T_{N,2}(s) \leq C(s_{0}) N^{-2/3} \exp(-s), \text{ for all } s \geq s_{0}.$$
**Summing up.** Combining the bounds on $\mathcal{T}_{N,1}$ and $\mathcal{T}_{N,2}$, we have, uniformly for $s \geq s_0$

$$|\partial_s \theta_{n,N}(x_{n,N}(s)) - A'(s)| \leq C(s_0)N^{-2/3}\exp(-s).$$

By the discussion following (74), we obtain the desired bound on $|\psi_\tau'(s) - G'(s)|$ in (77).

### 5.3.3 Improved bound for $|\psi_\tau - G|$ 

The bound on $|\psi_\tau'(s) - G'(s)|$, together with (67), can lead to a tighter bound for $|\psi_\tau(s) - G(s)|$ as the following:

$$|\psi_\tau(s) - G(s)| = \left| \int_s^{2s} [\psi_\tau'(t) - G'(t)]dt - [\psi_\tau(2s) - G(2s)] \right|$$

$$\leq \int_s^{2s} |\psi_\tau'(t) - G'(t)| dt + |\psi_\tau(2s) - G(2s)|$$

$$\leq \int_s^{2s} C(s_0)N^{-2/3}e^{-t}dt + C(s_0)N^{-2/3}\exp(-s) \leq C(s_0)N^{-2/3}\exp(-s).$$

This is exactly what we have claimed in Proposition 2.

### 5.4 Asymptotics for Quantities Related to $\phi_\tau(s)$

In this part, we employ a trick in [15] to transfer the bounds on the quantities related to $\psi_\tau$ to those related to $\phi_\tau$.

Recall that, for $\tilde{\rho}_N = 1 + O(N^{-1})$ [see A.1 for its proof],

$$\phi_\tau(s) = \frac{1}{\sqrt{2}}\tilde{\rho}_N F_{n-2,N}(x_{n-1,N-1}(s)) \frac{\mu_{n-2,N}}{x_{n-1,N-1}(s)}.$$  

If the $x_{n-1,N-1}(s)$ term on the right side were $x_{n-2,N}(s)$, then all the bounds we have proved for $\psi_\tau$ would also be valid for $\phi_\tau$. As this is not the case, we introduce a new independent variable $s'$ as:

$$x_{n-1,N-1}(s) = x_{n-2,N}(s'),$$

i.e., $s' = (\mu_{n-1,N-1} - \tilde{\mu}_{n-2,N})/\sigma_{n-2,N} + s\tilde{\sigma}_{n-1,N-1}/\tilde{\sigma}_{n-2,N}$. Then, $\phi_\tau$ can be rewritten as

$$\phi_\tau(s) = \frac{1}{\sqrt{2}}\tilde{\rho}_N F_{n-2,N}(x_{n-2,N}(s')) \frac{\mu_{n-2,N}}{x_{n-2,N}(s')} = \frac{1}{\sqrt{2}}\tilde{\rho}_N \theta_{n-2,N}(x_{n-2,N}(s')).$$

Recall the definition of $\Delta_N$ in (33), we have $s' = s = \Delta_N + [\tilde{\sigma}_{n-1,N-1}\tilde{\sigma}_{n-2,N}]s$, with

$$\Delta_N = O(N^{-1/3}), \quad 1 \leq \tilde{\sigma}_{n-1,N-1}\tilde{\sigma}_{n-2,N} = 1 + O(N^{-1}).$$

**Bounds for $|\phi_\tau(s)|$ and $|\phi_\tau'(s)|$.** Recall previous bounds on $|\theta_{n,N}(x_{n,N}(s))|$ and $|\partial_s \theta_{n,N}(x_{n,N}(s))|$. Together with (77), they imply that, for all $s \geq s_0$,

$$|\phi_\tau(s)| \leq C(s_0)\exp(-s') \leq C(s_0)\exp(-s),$$

and

$$|\phi_\tau'(s)| = \frac{1}{\sqrt{2}}\tilde{\rho}_N |\partial_s \theta_{n-2,N}(x_{n-2,N}(s'))| = \frac{1}{\sqrt{2}}\tilde{\rho}_N |\partial_s \theta_{n-2,N}(x_{n-2,N}(s'))| \frac{ds'}{ds}$$

$$\leq C(s_0)\exp(-s') \frac{\tilde{\sigma}_{n-1,N-1}}{\tilde{\sigma}_{n-2,N}} \leq C(s_0)\exp(-s).$$

---

5 The readers are expected not to confuse it with the $s'$ previously appeared in Section 3.1
Bounds for $|φ_r(s) - G_N(s)|$ and $|φ_r'(s) - G'_N(s)|$. We consider $|φ_r(s) - G_N(s)|$ in detail and the derivation for the bound on $|φ_r'(s) - G'_N(s)|$ is essentially the same.

By the definition of $s'$ and the identity $Ai''(s) = sAi(s)$, we obtain the Taylor expansion

$$G(s') = G(s) + (s' - s)G'(s) + \frac{1}{2}(s' - s)^2G''(s'),$$

with $s'$ lying in between $s$ and $s'$. By previous discussion on $|ψ_r(s) - G(s)|$, this leads to

$$|φ_r(s) - G_N(s)| \leq C(s_0)N^{-2/3}\exp(-s') + CN^{-1}|sAi'(s)| + C(s' - s)^2|s^*Ai(s^*)|$$

(78)

To further bound the last term, we split $[s_0, ∞)$ into $I_{1,N} \cup I_{2,N}$. For $s \in I_{1,N}$,

$$(s - s')^2 = [Δ_N + (\frac{2n-1,N-1}{σ_{n-2,N}} - 1)1]^2 \leq [CN^{-1/3} + CN^{-1}s]^2 \leq (CN^{-2/3} ∧ 1).$$

So $|s^*| \leq |s| + 1$, and Lemma 1 implies that

$$C(s - s')^2|s^*Ai(s^*)| \leq C(s_0)N^{-2/3}\exp(-s).$$

On $I_{2,N}$, (77) implies that $s' ≥ s/2$, and hence $s^* ≥ s/2$. Together with Lemma 1 this implies

$$C(s' - s)^2|s^*Ai(s^*)| \leq Cs^{-4}⋅|s^*|^7Ai(s^*)| \leq CN^{-2/3}\exp(-s).$$

Therefore, we have shown that, for all $s ≥ s_0$, the last term in (78) is further controlled by $C(s_0)N^{-2/3}\exp(-s)$, which in turn gives the desired bound for $|φ_r - G_N|$. It is not hard to check that all the $C(s_0)$ functions in the above analysis could be continuous and non-increasing.

Acknowledgment

I am most grateful to Professor Iain Johnstone for numerous discussions. Thanks also go to Professor Debasish Paul for kindly sharing an unpublished manuscript. I am grateful to the Editor, an Associate Editor and an anonymous referee for their helpful comments that lead to improvement on the presentation of the paper. A Appendix

In the appendix, we collect technical details for that lead to some of the claims previously made in the main text. [A.1] gives proofs to properties of a number of constants. [A.2] works out the details on the choice $s_1$, which was used to decompose the interval $[s_0, ∞)$ in Section 5.

A.1 Properties of $β_N$, $ρ_N$, $β̃_N$, $Δ_N$ and $σ_{n-1,N-1}/σ_{n-2,N}$

Property of $β_N$. We are to show that $β_N = \frac{1}{V^2} + O(N^{-1})$. By definition, we know

$$β_N = \frac{1}{2} \int_{-∞}^{∞} φ_r(s)ds = \frac{1}{2} \int_{0}^{∞} φ(x; α)dx = \frac{N^{1/4}(n - 1)^{1/4}\Gamma^{1/2}(N + 1)}{2\sqrt{2}\Gamma^{1/2}(n)} \times \int_{0}^{∞} x^{(α-1)/2}e^{-x/2}L_N^α(x)dx = \frac{2^{-α/2}N^{1/4}(n - 1)^{1/4}\Gamma^{1/2}(n)Γ(\frac{1}{2}(N + 3))}{(N + 1)\Gamma^{1/2}(N + 1)Γ(\frac{1}{2}(n + 1))}.$$
Applying Sterling’s formula $\Gamma(z) = (2\pi/z)^{1/2}(z/e)^z(1 + O(z^{-1}))$, we obtain that

$$
\beta_N = \frac{(2\pi/n)^{1/4}}{[2\pi/(N + 1)]^{1/4}[(N + 1)/e]^{(N+1)/2}} \frac{(N + 3)/(2e)^{(N+3)/2}}{[4\pi/(n + 1)]^{1/2}[(n + 1)/(2e)]^{(n+1)/2}} \times \frac{2^{-n/2}N^{1/4(n - 1)/4}}{N + 1} (1 + O(N^{-1}))
$$

$$= \frac{1}{\sqrt{2e}} \left(1 - \frac{1}{n + 1}\right)^{n/2} \left(1 + \frac{2}{N + 1}\right)^{(N+1)/2+3/4} (1 + O(N^{-1}))
$$

$$= \frac{1}{\sqrt{2}} + O(N^{-1}).
$$

**Properties $\rho_N$ and $\tilde{\rho}_N$.** We want to show that $\rho_N, \tilde{\rho}_N = 1 + O(N^{-1})$. Consider $\rho_N$ first. By definition, we have

$$\rho_N = \frac{N^{1/4(n - 1)/4}\tilde{\sigma}_{n-1,N-1}N^{1/2}}{\mu_{n,N}} = \frac{N^{1/4(n - 1)/4}\tilde{\sigma}_{n-1,N-1}}{\mu_{n-1,N-1}}.
$$

Plugging in the definition of $\tilde{\sigma}_{n-1,N-1}$ and $\tilde{\mu}_{n-1,N-1}$, we obtain that

$$\rho_N = N^{1/4(n - 1)/4} \left(\sqrt{N - \frac{1}{2}} + \sqrt{n - \frac{1}{2}}\right)^{-1/2} \left(\frac{1}{\sqrt{N - \frac{1}{2}}} + \frac{1}{\sqrt{n - \frac{1}{2}}}\right)^{1/2}
$$

$$= \left(\frac{N}{N - \frac{1}{2}}\right)^{1/4} \left(\frac{n - 1}{n - \frac{1}{2}}\right)^{1/4} = 1 + O(N^{-1}).
$$

For $\tilde{\rho}_N$, we have

$$\tilde{\rho}_N = \frac{N^{1/4(n - 1)/4}\tilde{\sigma}_{n-2,N}N^{3/4}}{\tilde{\mu}_{n-2,N}} = \frac{\tilde{\sigma}_{n-1,N-1}N^{1/4(n - 1)/4}\tilde{\sigma}_{n-2,N}}{\tilde{\sigma}_{n-2,N}} N^{1/4(n - 1)/4} \left(\sqrt{N + \frac{1}{2}} + \sqrt{n - \frac{3}{2}}\right)^{-1/2} \left(\frac{1}{\sqrt{N + \frac{1}{2}}} + \frac{1}{\sqrt{n - \frac{3}{2}}}\right)^{1/2}
$$

$$= \frac{\sigma_{n-1,N-1}}{\sigma_{n-2,N}} \left(\frac{N}{N + \frac{1}{2}}\right)^{1/4} \left(\frac{n - 1}{n - \frac{3}{2}}\right)^{1/4} = 1 + O(N^{-1}).
$$

The last equality holds since $\tilde{\sigma}_{n-1,N-1}/\tilde{\sigma}_{n-2,N} = 1 + O(N^{-1})$ as claimed in [33], which is to be shown below.

**Property of $\Delta_N$.** Recall the definition $\Delta_N = (\tilde{\mu}_{n-1,N-1} - \tilde{\mu}_{n-2,N})/\tilde{\sigma}_{n-2,N}$. By [10] A.1.2, the numerator $\tilde{\mu}_{n-1,N-1} - \tilde{\mu}_{n-2,N} = O(1)$. For the denominator, let $\gamma_{n,N} = (n - \frac{3}{2})/(N + \frac{1}{2})$, we then have

$$\frac{1}{\tilde{\sigma}_{n-2,N}} = \left(\sqrt{N + \frac{1}{2}} + \sqrt{n - \frac{3}{2}}\right)^{-1} \left(\frac{1}{\sqrt{N + \frac{1}{2}}} + \frac{1}{\sqrt{n - \frac{3}{2}}}\right)^{-1/3}
$$

$$= \frac{1}{1 + \gamma_{n,N}^{1/2}} \left(1 + \gamma_{n,N}^{-1/2}\right) (N + \frac{1}{2})^{-1/3} = O(N^{-1/3}).$$
The last equality holds since $\gamma_n N$ is bounded below for all $n > N$. Combining the two parts, we establish that $\Delta_N = O(N^{-1/3})$.

Property of $\tilde{\sigma}_{n-1,N-1}/\tilde{\sigma}_{n-2,N}$. We now switch to prove that

$$1 \leq \tilde{\sigma}_{n-1,N-1}/\tilde{\sigma}_{n-2,N} = 1 + O(N^{-1}).$$

[10] A.1.3 showed that $\tilde{\sigma}_{n-1,N-1}/\tilde{\sigma}_{n-2,N} = 1 + O(N^{-1})$. On the other hand, we have from the second last display of [10] A.1.3 that

$$\left(\frac{\tilde{\sigma}_{n-1,N-1}}{\tilde{\sigma}_{n-2,N}}\right)^3 = \left[1 + \sqrt{\frac{n}{N}} - \frac{\sqrt{n}}{n + N} + O(n^{-2})\right] \left[1 + \frac{1}{2} \left(\frac{1}{n} + \frac{1}{N}\right) + O(n^{-2})\right].$$

Both terms become greater than 1 when $N \geq N_0(\gamma)$, and hence $\tilde{\sigma}_{n-1,N-1}/\tilde{\sigma}_{n-2,N} \geq 1$ for large $N$. Actually, the inequality holds for any $n > N \geq 2$. However, what we have proved here is sufficient for our argument in Section 5.4.

A.2 Choice of $s_1$ and its consequences

The key point in our choice of $s_1$ is to ensure that when $s \geq s_1$, we have

$$\frac{2}{3} \kappa_N \zeta^{3/2} \geq \frac{3}{2} s. \quad (79)$$

To this end, recall that in [15] A.8, one could choose $\tilde{s}_1(\gamma) = C(\gamma)(1 + \delta)$ with some $\delta > 0$, such that when $s \geq \tilde{s}_1(\gamma)$, we have $\sqrt{\tilde{f}(\xi)} \geq 2/\tilde{\sigma}_{n,N}$ and hence if $s \geq 4\tilde{s}_1(\gamma)$,

$$\frac{2}{3} \kappa_N \zeta^{3/2} = \kappa_N \int_{\xi_+}^{\xi} \sqrt{\tilde{f}(z)} dz \geq \kappa_N \frac{2}{\tilde{\sigma}_{n,N}} (s - \tilde{s}_1(\gamma)) \frac{\tilde{\sigma}_{n,N}}{\kappa_N} = 2(s - \tilde{s}_1(\gamma)) \geq \frac{3}{2} s.$$  

Moreover, by the analysis in [10] A.6.4, $\tilde{s}_1(\gamma)$ could be chosen independently of $\gamma$ and hence we could define our $s_1$ to be

$$s_1 = 4\tilde{s}_1$$

which is independent of $\gamma$ and such that (79) holds. Moreover, we also require that $s_1 \geq 1$.

After specifying our choice of $s_1$, we spell out two of its consequences. The first of them is that when $s \geq s_1 \geq 1$,

$$\mathcal{E}^{-1}(\kappa_N^{2/3} \zeta) \leq C \exp(-3s/2) \leq C \exp(-s). \quad (80)$$

This is from the observation that $\mathcal{E}(x) \geq C \exp(2x^{3/2}/3)$ and hence

$$\mathcal{E}^{-1}(\kappa_N^{2/3} \zeta) \leq C \exp \left(\frac{2}{3} \kappa_N \zeta^{3/2}\right) \leq C \exp(-3s/2).$$

The other consequence is about the behavior of $s'$ defined in [76] when $s \geq s_1$. Remembering that $s_1 \geq 1$, we then have that when $s \geq s_1$ and $N \geq N_0(\gamma)$,

$$s' - \frac{s}{2} = \Delta_N + \left(\frac{\tilde{\sigma}_{n-1,N-1}}{\tilde{\sigma}_{n-2,N}} - \frac{1}{2}\right) s \geq \Delta_N + \frac{s_1}{2} \geq \Delta_N + \frac{1}{2} \geq 0. \quad (81)$$

The last inequality holds when $N \geq N_0(\gamma)$, for $\Delta_N = O(N^{-1/3})$.
